Determinants of litter decomposition rates in a tropical forest: functional traits, phylogeny and ecological succession. – *Oikos* doi: 10.1111/oik.03670

## Appendix 1

### Correlations between input variables

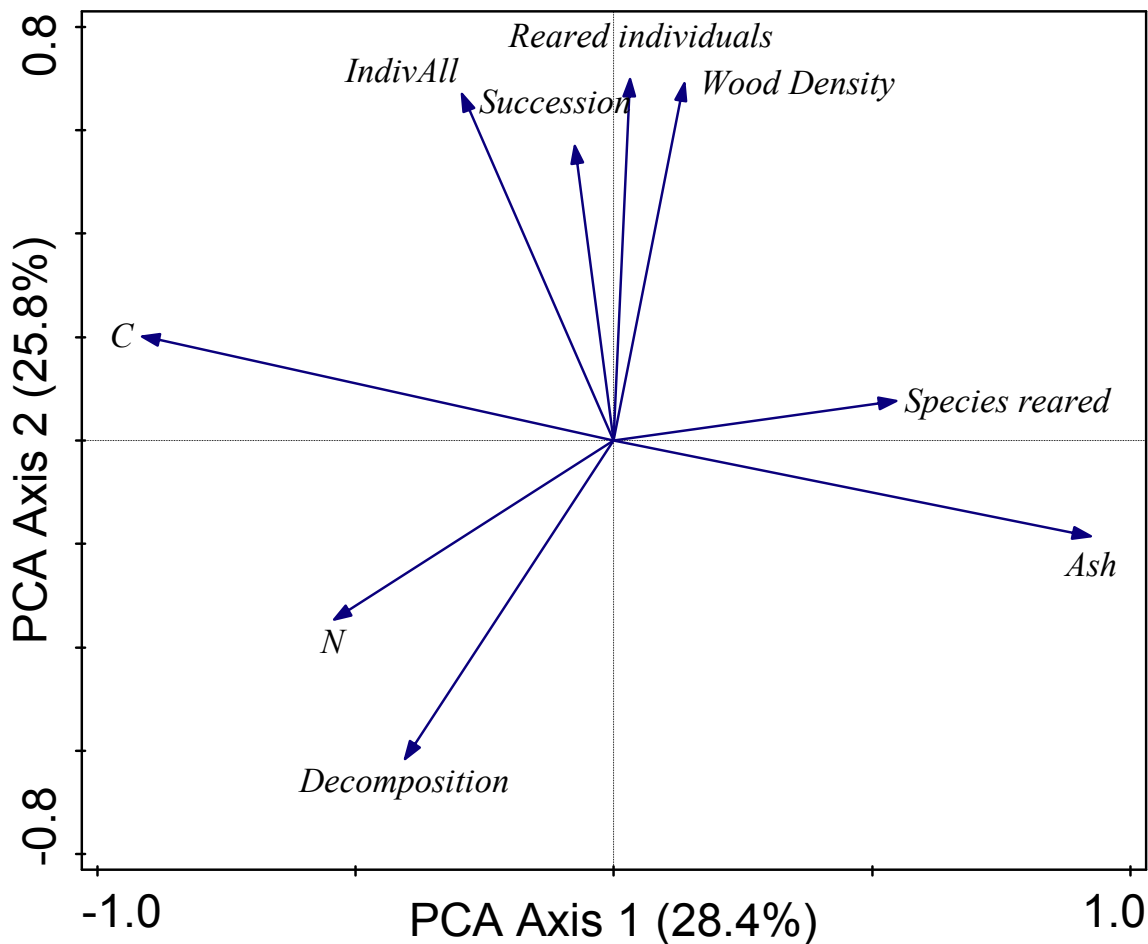

Figure A1. Principal component analysis (PCA) of response variable (decomposition rate) and explanatory variables (physiochemical properties of plant species – nitrogen (N), carbon (C), wood density, ash; plant successional status (succession) and associated insects herbivory rate (recorded individuals of insect – number of externally feeding individuals collected (All individuals), species reared and reared individuals). First two canonical axes explained 54,2 % of variability.

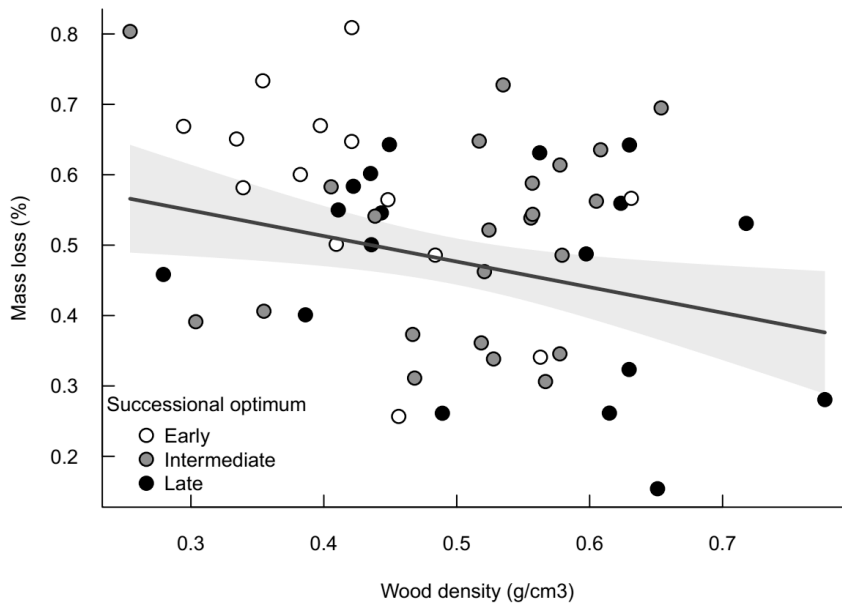

Figure A2. Negative linear relationship between leaves decomposition (the mass loss in %) and wood density of individual tree species ( $y = 0.659 - 0.366x$ ,  $p = 0.015$ ,  $R^2 = 0.085$ ).

Figure A3. Positive relationship between wood density and plant successional status ( $y = 0.494 + 0.136x$ ,  $p < 0.001$ ,  $R^2 = 0.147$ ). The colours represent: early (blank circle), intermediate (grey circles) and late (black circles) successional optimum

Table A1. Correlation coefficients between decomposition rate, physicochemical properties of leaves and focal plant species, plant successional status and associated insects herbivory rate (Individuals recorded - number of externally feeding individuals collected, Species and Individuals reared – number of species and individuals that reared while they were fed by individual plant species). Significantly correlated parameters are shown in bold.

## Appendix 2

### Comparison of leaf-litter water content between primary and secondary forest sites

Humidity of forest understorey and related values of leaf litter moisture has been reported to have profound effect on litter decaying rate. Therefore we carried out additional measurements of the litter water content in two focal habitat types: primary and young secondary forest.

Samples of leaf litter were collected from 12:00 to 13:15 on a sunny day on 14 December 2015 near Ohu village in Papua New Guinea. It is noteworthy that a heavy rainfall was recorded during the preceding night. A handful of leaf litter was collected from 20 sites (located within a ~1 km radius) in each of the habitat type: primary and young secondary forest (3–4 years old abandoned gardens). Samples of litter contained exposed particles from a top layer as well as more damp covered parts of litter. This was stored in plastic zip-lock bags while only bags without an air leak were used in order to prevent any litter desiccation. Each bag containing leaf-litter was weighted shortly after the collection finished. After first weighing, bags were cut opened and placed into a drier for 5 days and samples of leaf-litter were reweighed again afterwards. Once dry each empty plastic bag was also weighted and its mass was deducted from a litter mass. The mass differences between fresh and dried leaf-litter provided a percentage water content of each collected litter samples. Difference in water litter content between primary and secondary forest was analysed by one-way ANOVA test. Data were visualised with package ggplot2 (Wickham 2009) using again RStudio.

We found significant difference in leaf litter water content between samples collected in primary and secondary forest (ANOVA,  $F_{19,19} = 19.2578$ ,  $p < 0.001$ ). Evidently leaf-litter in secondary forest sites was more exposed to the direct sunlight having lower values of water content compared with leaf-litter in primary forest (Fig. A4)

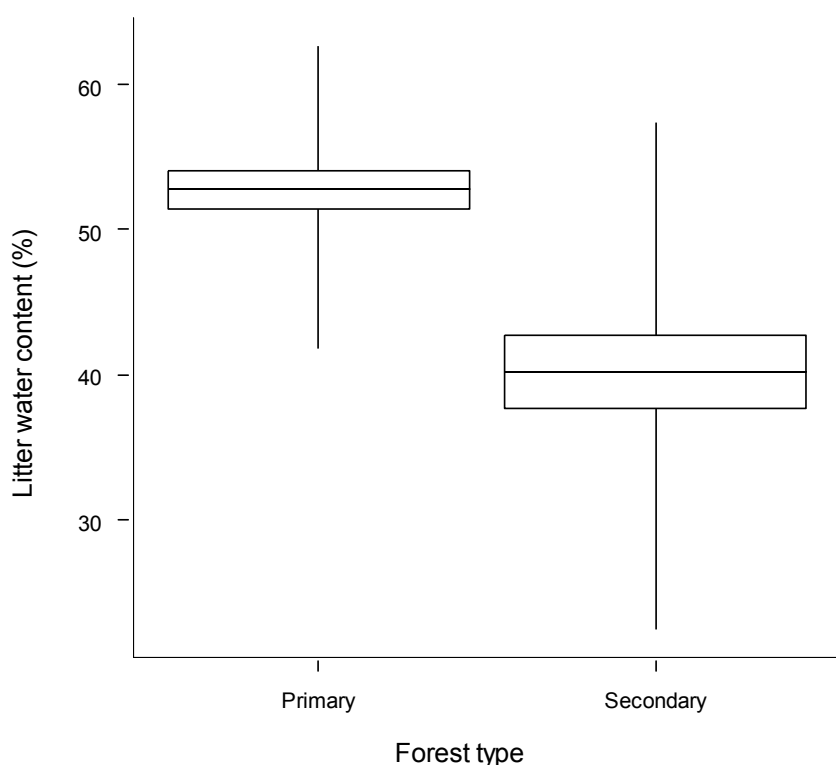

Figure A4. Percentage values of water content (mean  $\pm$  SE, min. and max.) in leaf-litter collected in primary and secondary forest sites.

## Appendix 3

### List of tree species used in the analysis

Table A2. List of plant species that were used in analysis of leaf-litter decay. Successional status with negative values indicate to early-successional species while high positive values indicate to climax species. Values of relative weight loss obtained during leaf decay experiment in primary and secondary forest are listed for individual plant species.

## Appendix 4

Table A3. Results of model fitting tests on the evolution of initial nitrogen content (NITRO), successional optima (OPTIMA) and wood density (WOOD) under eight common models of evolution: white noise model (White); Pagel's (1999) lambda transformation (Lambda); Ornstein-Uhlenbeck model (OU); punctuational (speciational) model of trait evolution (Kappa); a time-dependent model of trait evolution (Delta); diffusion model with linear trend in rates through time (Trend); brownian motion model (BM); early burst model (EB). P-values correspond to likelihood ratio test of a given model and the white noise model.
