The National Park Service, Natural Resource Program Center publishes a range of reports that address natural resource topics of interest and applicability to a broad audience in the National Park Service and others in natural resource management, including scientists, conservation and environmental constituencies, and the public.

The Natural Resource Report Series is used to disseminate high-priority, current natural resource management information with managerial application. The series targets a general, diverse audience, and may contain NPS policy considerations or address sensitive issues of management applicability.

All manuscripts in the series receive the appropriate level of peer review to ensure that the information is scientifically credible, technically accurate, appropriately written for the intended audience, and designed and published in a professional manner.

This report received informal peer review by subject-matter experts who were not directly involved in the collection, analysis, or reporting of the data.

Views, statements, findings, conclusions, recommendations, and data in this report do not necessarily reflect views and policies of the National Park Service, U.S. Department of the Interior. Mention of trade names or commercial products does not constitute endorsement or recommendation for use by the U.S. Government.

This report is available from NPS Chihuahuan Desert Network website (<http://science.nature.nps.gov/im/units/chdn/>) and the Natural Resource Publications Management website (<http://www.nature.nps.gov/publications/NRPM>).

Executive Summary

The National Park Service-Chihuahuan Desert Network (NPS-CHDN), Big Bend National Park (BIBE), and Rio Grande National Wild and Scenic River (RIGR), with assistance of the National Vegetation Inventory Program (NVIP) staff, are preparing to conduct vegetation classification plot sampling in support of creating a vegetation map and geodatabase beginning in September 2010. As part of study plan (NPS-BIBE/RIGR 2010) preparation, a preliminary list of 33 ecological systems and component vegetation alliances and plant associations was prepared from the NatureServe Explorer Web site (2010) and vetted by the BIBE/RIGR species list to inform field crews, improve planning decisions, and generate cost estimates for project tasks.

The purpose of Task 3.0: Vegetation Classification List Update for BIBE/RIGR, is to refine and, when appropriate, update the preliminary classification list of vegetation occurring within BIBE/RIGR to the vegetation alliance and plant association levels of the National Vegetation Classification (NVC) maintained by NatureServe. The sources of new information include the legacy data evaluated under Task 1.0 of this project and discussions with researchers sampling classification data on-park.

The plant species list provided by the NPS-CHDN Biological Science Technician Missy Powell and BIBE/RIGR Botanist Joe Sirotnak numbered 1,701 species and varieties (NPS-BIBE/RIGR 2010) and, with more than 40 legacy research projects evaluated, formed the basis for selecting and updating potential vegetation alliances and plant associations occurring within BIBE/RIGR. The updated list presented in tabular form by physiognomic types herein presents 123 vegetation alliances and 192 plant associations that potentially occur in BIBE/RIGR. There are 34 potential forest and woodland alliances comprising 63 potential associations; 42 potential shrubland, dwarf-shrubland, and shrub herbaceous alliances comprising 80 potential associations; and 47 potential herbaceous and sparse alliances comprising 49 potential associations. As deemed appropriate from the NVC and from legacy research, semi-natural vegetation types characterized by nonnative plant species were included in this classification (representing nine vegetation alliances and seven plant associations).

This vegetation classification list will be invaluable as a guidance tool for field crews to apply provisional names to vegetation stands sampled in the field with classification plots, prior to formal classification using statistical analyses. By reviewing this classification list, field crews will also be able to determine when they have encountered a previously undescribed vegetation type. A structured alliance/association list also allows field crews to tally classification plot and observation point numbers on a daily or trip basis to reduce unnecessary field sampling and also to ensure distribution of plots to sample diversity parkwide, saving project time and funding while ensuring thorough vegetation type sampling.

Introduction

CHDN and BIBE/RIGR, with the assistance of the NVIP staff, are preparing to conduct vegetation classification plot sampling in support of creating a vegetation map and geodatabase beginning in September 2010. Field crews benefit from having a preliminary list of vegetation alliances and plant associations from which to inform landscape observations of vegetation stands, classification plot site selection, plot density, and community type decisions when sampling vegetation types for classification under the National Vegetation Classification (NVC). The list provided herein was prepared using legacy data (analyzed in a companion research report, Task 1.0: Legacy Data Evaluation for BIBE/RIGR), interviews with researchers directly involved in legacy data gathering, the BIBE/RIGR plant species list (provided as Appendix 1), and NatureServe's Explorer Web site (NatureServe 2010).

The NVC, as developed by The Nature Conservancy (TNC) and currently maintained by NatureServe, represents a national system containing eight levels: (1) Formation Class, (2) Formation Subclass, (3) Formation, (4) Division, (5) Macrogroup, (6) Group, (7) Alliance, and (8) Association with the finest level being the plant association. Alliances are usually aggregations of associations that are physiognomically uniform and share one or more characteristic or diagnostic species. An association is defined as a plant community or type with a consistent species composition, uniform physiognomy, and homogenous habitat conditions (Flahault and Schroter 1910). The plant association or community type is determined by environmental patterns and disturbance processes.

Associations are separated from alliances through the use of total floristic composition and are named by the most dominant and/or indicator species. For the name or title assigned to an association or alliance, a single dominant species may be used (*Prosopis glandulosa* Woodland). If two dominant species of the same stratum are used they are separated by a dash (*Larrea tridentata* – *Parthenium incanum* Shrubland). If two dominant species occur in different strata, then a slash is used to separate them (*Prosopis glandulosa* / *Bouteloua eriopoda* Woodland). Parentheses are used when the diagnostic species are not consistently present in the association or alliance (*Distichlis spicata* – [*Hordeum jubatum*] Temporarily Flooded Herbaceous Alliance).

The purpose of the NVC is to provide a complete, standardized listing and description of all vegetation types that represent variation in biological diversity at the community level and to identify those communities that require protection (Grossman et al. 1994). The NVC focuses on existing vegetation rather than potential natural vegetation, climax vegetation, or physical habitats. Because it is not restricted to static vegetation types, classification units are useful both for inventory, site description, and as the basis for building dynamic ecological models. The NVC also includes vegetation along the natural-invasive-cultural (semi-natural and modified) continuum, but it emphasizes natural communities as the focus of biodiversity protection.

The project minimum mapping unit (MMU) is 0.5 hectare (1.24 acres) and vegetation stands are sampled using classification plots. Typically, between three to five classification plots are required to adequately describe most plant associations. Small, unique vegetation patches or stands are often termed “park specials” in the NVIP because of their value for overall management prescriptions, but they are less than the project MMU. Resource management staff

at BIBE/RIGR identified such stands of unique vegetation at the BIBE/RIGR Study Plan (2010) kick-off meeting.

Background

The following discussion was excerpted in part from the BIBE/RIGR Study Plan (2010) and users are encouraged to review the plan to place this classification research study in context with the larger project. The Rio Grande, Chisos Mountains, and other high-elevation sites support most of the woodland and forest vegetation types, which cover less than 10% of the parks. The majority of BIBE/RIGR vegetation consists of thornscrub shrubland communities, stands of desert grassland, and sparsely vegetated rock outcrops.

The Big Bend region has been classified as the Chihuahuan Desert Province (Dry Domain [300], Tropical/Subtropical Desert Division [320]) (Bailey 1995). The Texas Parks and Wildlife Department (TPWD 2010) describe this region and reach of the Rio Grande under the Chihuahuan Biotic Province; Trans-Pecos Natural Region; and the Level III Ecoregion of the Chihuahuan Desert. Six major vegetation types are described in the BIBE Fire Management Plan (2005); which include: (1) Floodplain/Upland Riparian, (2) Scrub Desert, (3) High Desert Grasslands, (4) Shrub Woodland, (5) Grassy Woodlands, and (6) Forests. Major vegetation types or categories were defined by Plumb (1988 and 1993) and Brown (1994 and 2000) and are summarized from the BIBE Fire Management Plan (2005) and the RIGR General Management Plan (2004a) as follows:

Floodplain/Upland Riparian: consists of two general cover-mapping categories - Mixed Riparian and Desert Willow from Plumb (1993) formed this vegetation category. The Rio Grande with a high water table and dependable year-round flow supports dense stands of vegetation, and although approximately 5% to 10% of the project area, forms a vital habitat for wildlife. Upstream dams in New Mexico and Colorado now capture spring floodwaters. The Rio Conchos, 100 miles upstream, draining Mexican highlands and smaller tributaries provide valuable surface flows. Upland Springs: springs, seeps and tinajas provide water for wildlife and occur regularly in the mountains and on the low-elevation desert floor. Salt-cedar (*Tamarix* spp.) is being systematically removed from springs and seeps allowing native plants, including Fremont cottonwood (*Populus fremontii*) and honey mesquite (*Prosopis glandulosa*) trees, to reestablish.

Scrub Desert: this physiognomic type was compiled from five cover-mapping categories from Plumb (1993); Creosote bush-Lechuguilla-Grass, Creosote bush-Lechuguilla-Prickly Pear, Creosote bush-Tarbush, Creosote bush-Yucca-Grass, and Lechuguilla-Candellia-Hetchia. Desert scrub is characterized by shrubs (creosote bush, mariola, and ocotillo) and succulents (prickly pear, lechuguilla, and Texas hetchia or false-agave). Grasses are understory and usually provide insufficient fuels to carry fire. Scrub Desert occurs over 50% of the park between the low-lying floodplains (~1,700 ft) to mid-elevation desert grasslands (~3,000 ft).

High Desert Grasslands: represent the most diverse plant communities exhibiting the highest species per unit area. High desert grasslands cover about 40% of BIBE ranging from ~3,000 ft to ~5,000 ft elevation with scattered plants occurring at higher elevations of the Chisos Mountains.

High Desert Grasslands support some shrubs, low-growing trees, and cacti that are largely confined to drainages (supporting little grass cover) and to areas of rocky and shallow soils.

Shrub Woodland: this vegetation structure includes three cover-mapping categories from Plumb (1993): they are Mixed Scrub, Oak Scrub, and Mixed Oak-Shrub Woodlands. Shrubby woodlands include many that are scattered on the foothills and slopes of the Chisos and Dead Horse (Sierra del Caballo Muerto) mountains. Elevation range typically occupied by this type varies from ~4,500 ft at Green Gulch to ~5,500 ft near Chisos Basin.

Grassy Woodlands: include three cover-mapping categories from Plumb (1993); they are Pinyon-Juniper-Grass, Pinyon-Oak-Juniper, and Forest-Meadow. Elevation ranges from ~5,500 ft to ~7,200 ft where most stands occur.

Forest: stands include two cover-mapping categories from Plumb (1993); they are Pinyon-Talus and Oak-Ponderosa Pine-Cypress. Forests occur above ~6,000 ft and form mosaics of conifer stands and grassy woodlands.

Distinct Forest and Woodland Populations: Arizona cypress and Douglas-fir in Boot Canyon, red oak in West Chisos Mountains, quaking aspen on the northwest side of Emory Peak, one lateleaf oak, small stands of netleaf oak in the high Chisos Mountains, Texas madrone on north-facing slopes and in canyons, and Chisos hophornbeam on slopes north of Emory Peak and Crown Mountain (also in Boot Canyon, near Pinnacles Trail, and upper Cattail Canyon). Rare forest stands include ponderosa pine in Boot Canyon, Pine Canyon, and Crown Mountain; bigtooth maple in canyons and on north-facing slopes; species of orchids scattered throughout the Chisos Mountains on appropriate habitat; and Guadalupe fescue on the moist slopes of Boot Canyon.

Project area vegetation distribution is influenced by several factors (ecologic drivers) that include hydrology, elevation, slope, aspect/slope exposure, precipitation patterns, temperature extremes, topographic position, geology, and soils. The environmental drivers have resulted in a unique assemblage of plant species and plant communities. The environmental drivers are discussed in detail and used to prepare bio-physical unit maps in support of field crews in the companion study (Task 2.0: Gradsect and Field Sampling Plan for BIBE/RIGR).

Rainfall runoff flows to the Rio Grande via desert washes, arroyos, and Terlingua and Tornillo creeks within BIBE. Flows from the Rio Conchos emanate from Mexico approximately 100 miles upstream from BIBE and contribute to surface and groundwater quantities in the BIBE/RIGR reach. The Rio Grande annual flows and sediment delivery/removal have been controlled by upstream dams and groundwater pumping for many decades resulting in diminished overbank flooding and allowing bank-armoring vegetation to establish including salt-cedar (*Tamarix* spp.), giant reed (*Arundo donax*), Johnson grass (*Sorghum halepense*), buffelgrass (*Cenchrus ciliaris*), and Bermuda grass (*Cynodon dactylon*). These invasive, nonnative species have become a management concern requiring park resources to monitor populations and attempt focused control and eradication. Water quality may also affect riparian and wetland plant communities along the Rio Grande due to the release of treated sewage from several cities upstream of RIGR. Nonnative vegetation types are routinely sampled for classification and mapping purposes under the NVIP.

Legacy Data

Legacy data are existing qualitative and quantitative vegetation information collected in support of a variety of BIBE/RIGR research projects over the years. Please refer to the companion study (Task 1.0: Legacy Data Evaluation for BIBE/RIGR) and the BIBE/RIGR Study Plan (2010) for an in-depth summary of this project task.

Plant species list development for BIBE/RIGR was critical to this project task and two principle legacy studies were undertaken to prepare a comprehensive floristic inventory. In the first, Dr. Richard Worthington (2002) submitted a working draft of plant species known to occur in BIBE/RIGR. The tabular data were divided into families and each taxa was described by scientific name and author, common name, and known location within the park units. Listed were 73 species of lichens, liverworts, and bryophytes and 1,013 species of vascular plants (including club mosses and ferns and fern allies).

Fenstermacher et al. (2008) conducted a floristic inventory from 2003-2006 over approximately 176,800 acres (71,548 ha) including the Dead Horse Mountains (Sierra del Caballo Muerto) in the northeastern and eastern portions of BIBE. The project elevation range was approximately 4,100 feet (1,250 meters); of the 3,796 plant specimens collected or examined as herbarium specimens, 662 species, 344 genera, and 91 families of vascular plants were identified. Twenty-four plant species are nonnative and of these three species are considered noxious and six species are considered invasive. Of significance floristically are the co-dominance of the families Poaceae and Asteraceae in terms of number of plant species per the total flora. Previously unknown BIBE plant species determined from this study were added to the species list provided in Appendix 1.

Also described in this paper are general habitats and common vegetation types that support a majority of the plant species, they are: (1) Mixed Desert Scrub; (2) Sotol-Yucca Grassland; (3) Chaparral; (4) Desert Canyon; (5) Rio Grande Riparian Corridor; (6) and Sandy Desert Arroyo. The dominant species comprising these habitats and types were used in part to develop the potential list of BIBE/RIGR vegetation alliances and plant associations (Table 1).

Results

The results of this research study are presented in table 1; a list of 123 vegetation alliances and 192 plant associations was prepared to inform field crew classification plot sampling and guide CHDN-BIBE/RIGR planning decisions in terms of timing and costs. A field oversight trip by Cogan Technology, Inc., ecologists on December 7, 2009, confirmed the presence of several of the upland and riparian/wetland plant communities included on the list. The final project classification list will appear in the final project report and will be based primarily on new plot data collected during 2010 and 2011 supplemented by legacy data. Additionally, an updated species list will be appended to the project final report and will be available in the project geodatabase.

The provisional vegetation classification list presented herein supports two BIBE/RIGR Study Plan assumptions relative to field data collection: (1) sufficient vegetation data occurs for this area that a relatively accurate preliminary list of ecological systems, vegetation alliances, and plant associations was created; and (2) new plant associations and possibly vegetation alliances will be classified from the plot database following field sampling for plots and accuracy assessment points. Vegetation alliances and plant associations listed in table 1 and having an element code (A. or CEGL, respectively) have been previously classified and described on the NatureServe Explorer Web site (www.natureserve.org/explorer/servlet/NatureServe?init=Ecol).

For the state of Texas, the NVC currently includes 118 environmental systems, 248 vegetation alliances, and 525 plant associations (NatureServe 2010). When vetted with the BIBE/RIGR species list of more than 1,700 taxa, the habitats known for the Trans-Pecos Region and acquired from more than 40 legacy studies, and an oversight field trip, this task resulted in identification of 33 ecological systems, 123 vegetation alliances, and 192 plant associations as possibly occurring within BIBE/RIGR. The BIBE/RIGR vegetation inventory area consists of approximately one million acres and an adequate level of sampling determined in the BIBE/RIGR Study Plan (2010) was estimated to be between 800 to 1,200 classification plots (the wide range accounts for some legacy plots potentially being determined useful instead of all new sampling).

Because vegetation alliances and plant associations can occur across more than one ecological system, that breakdown (featured in the BIBE/RIGR Study Plan [2010]) is not used in this task to avoid confusion and repetition. Rather, the list of plant communities presented herein is alphabetized and separated by physiognomic or structural types to be easily and efficiently accessed by field crews. Table 1A includes the forest and woodland types which number 34 vegetation alliances and 63 plant associations; Table 1B includes the shrubland, dwarf-shrubland, and shrub herbaceous types which number 42 vegetation alliances and 80 plant associations; and Table 1C includes the herbaceous and sparse types which number 47 vegetation alliances and 49 plant associations.

Two important uses of the BIBE/RIGR classification list by field crews are readily identified. The first important use includes documenting vegetation classification plot and observation point collection on a daily and field trip basis to avoid wasteful oversampling, but also to guide representative sampling across the project area so each type is represented by its diversity

parkwide. Rare types may be sampled as little as one time while common types may receive 10 to 15 classification plots to document regional diversity. The second important use is to apply the correct provisional plant community name sampled on the vegetation classification plot field form or in the electronic data logger.
