

THE OMAN BOTANIC GARDEN (1): THE VISION, EARLY PLANT COLLECTIONS AND PROPAGATION

Annette Patzelt¹, Leigh Morris², Laila Al Harthi¹, Ismail Al Rashdi¹ & Andrew Spalton³

ABSTRACT

The Oman Botanic Garden (OBG) is a new botanic garden which is being constructed on a 423ha site near to Muscat, the capital of Oman. Oman is floristically rich and is considered a centre of plant diversity in the Arabian Peninsula. The plan is that OBG will showcase this plant diversity, inform visitors of its value and provide a model for sustainability. This paper, part 1, covers the vision, early plant collections and propagation, and part 2, which will be included in *Sibbaldia* No. 7, will cover design, construction, interpretation and planting.

THE SITE

The Oman Botanic Garden (OBG), which is currently under construction, is to be a brand new, iconic botanic garden in the Sultanate of Oman. It is to be located on 423 hectares of natural habitat at Al Khoud, just to the west of the capital Muscat (Fig. 1). On the northern side of the site is a range of hills up to 281m high and within the site are a number of smaller hills (up to 170m). There are three wadis that cross the site, the largest of which is Wadi Sidr, which contains some pools of water throughout the year. The overall wide range of ground conditions will enable a large number of species to be grown within OBG, making it an excellent choice of location.

The site is remarkably green at certain times of the year and its most distinctive flora is the open woodland that dominates the wadi areas. The predominant species within this habitat is *Acacia tortilis*, but with occasional *Acacia ehrenbergiana*, *Prosopis cineraria* and *Ziziphus spina-christi*.

OMAN – A REGIONAL BIODIVERSITY HOTSPOT

The flora of Oman is floristically rich with a high degree of endemism. In the Sultanate of Oman c. 1,200 species of vascular plants are presently known (Miller & Cope, 1996).

Oman is a centre of plant diversity in the Arabian Peninsula, with 15.8% of the flora being range-restricted (Patzelt, 2008). Southern and central Oman have been identified as one of the world's 35 key biodiversity hotspots – areas that contain at least 1,500 endemic species of vascular plants (> 0.5% of the world's total), and where at least 70% of the natural vegetation has been lost (Mittermeier *et al.*, 2005). Of the total of 189 range-restricted species, 78 species are strictly endemic to the country, 48 are near-endemics and 63 are regional endemics (Patzelt, 2008).

There are currently 2,204 botanic gardens known in the world in 153 countries, but there are very few in the Middle East and South-West Asia (BGCI, 2001), although the area accounts for an estimated 58,500 species. OBG will be the sole garden in the area and aims to achieve a comprehensive *ex situ* conservation collection of native plants.

VISION AND OVERALL AIM

The vision is that “the Oman Botanic Garden as a new world class botanic garden conserves the unique botanical and ethnobotanical heritage of Oman and to ensure that the flora, heritage and ecosystems of Oman are valued by all”. The garden has the unique aim of propagating and displaying the complete indigenous flora of the Sultanate of Oman, within defined habitat zones (including large, iconic, environmentally controlled biomes for northern and southern flora), and aims to sustainably address the urgent need for conservation solutions to the biodiversity crisis.

The representation of a native flora in habitats has not had a prominent place in most botanic gardens. With both an interest in target 8 of the Global Strategy for Plant

Conservation and the development of a habitat-based garden, the OBG represents a new model for botanic gardens in the 21st century and is a groundbreaking initiative of *ex situ* conservation in Arabia. OBG sees its role in providing a model with conservation and sustainability at the forefront of its messages and the experience gained of vital importance for other major new gardens in development across Arabia.

SPECIFIC GOALS

OBG has a number of major objectives, as follows:

- Value the unique flora and ethnobotany of Oman
- Reflect and honour Oman's heritage
- Create an international 'must see' iconic visitor destination
- Provide a model for sustainability
- Exemplify the unique hospitality of Oman
- Lead the development of botanic gardens in Arabia
- Develop a cadre of professional Omani staff to manage the OBG
- Provide a major education resource in the field of biodiversity conservation
- Present and interpret exhibits of indigenous plant species and local cultivated crops, their habitats, traditional knowledge and animal–plant interactions
- Promote the use of indigenous plants for ornamental horticulture.

KEY CHALLENGES

OBG faces three broad key botanical and horticultural challenges during its development phase:

- Building up horticultural expertise in the team and the development of standard protocols in all areas of plant propagation and collection management for all Omani plants, including a wide range of range-restricted and threatened species.
- Identifying key botanical questions within the Omani flora and the development of the OBG team to be able to prioritize and answer them.
- Defining and developing the scientific impact of OBG in the wider *ex situ* conservation of Arabian plants and in the overall delivery on the Global Strategy for Plant Conservation (GSPC).

The development of such a botanic garden from scratch presents an outstanding example of *ex situ* conservation being undertaken in a botanic garden with national, regional and international significance. The planning for the development of OBG commenced in 2004. A master plan was submitted in 2006, the design finalized in 2008 and construction of phase one, the nursery, started at the beginning of 2008.

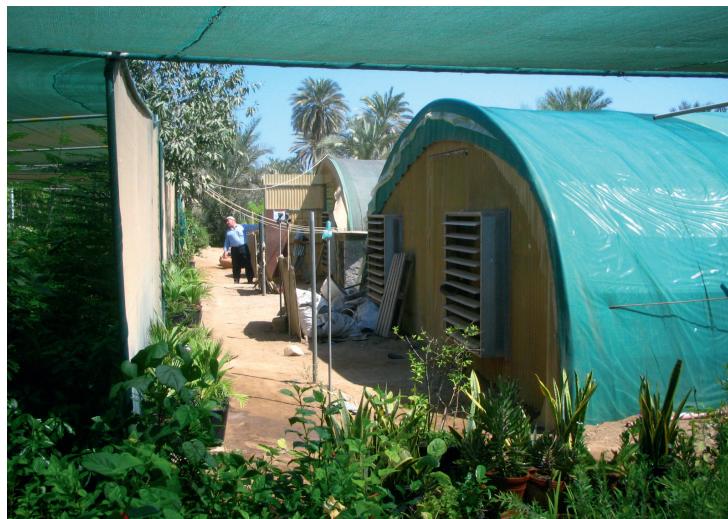

Fig. 2 Initial OBG propagation space was rented from a commercial nursery at Seeb, Muscat. Photo: Leigh Morris.

INITIAL PRODUCTION NURSERY

Overall, plant collections at OBG will eventually comprise of a living collection, seed bank, herbarium and also a digital herbarium. The initial priority for OBG, however, has been the propagation of the c. 400,000 indigenous and endemic living plants that are required for the planting of the habitat zones and all other planted areas within OBG. It is fundamental that when the OBG opens, the garden looks relatively established and contains as wide a selection of the Omani flora as possible.

Prior to the OBG project, very few Omani plants were in nursery cultivation. There are small nurseries in and around Muscat but these predominantly produce exotic plants for the ornamental market. The existence of these nurseries, however, proved to be extremely valuable to OBG, as space was rented within one for the propagation of Omani plants (Fig. 2). So, in early 2006, through these modest rented facilities and a single member of staff, OBG had a physical presence. Since then, both the OBG nursery team and the number of plants have increased and by June 2008 there were 20 staff and 51,851 individual plants on two rented nursery sites. This already therefore represented the largest documented Arabian plant collection.

PLANT COLLECTION

One of the key objectives of OBG is to cultivate and display only Omani plants and due to the lack of any significant numbers already in cultivation, this gave the OBG team the challenge of collecting all plant material from the wild. Diversity was of major importance, so collections were predominantly from seed; however, whole living plants and cuttings were also collected for certain species (but from a wide range of mother plants).

Fig. 3 Seed collection on Jabal Samhan in the Dhofar region of Oman being carried out by an OBG team member. Photo: Leigh Morris.

Fig. 4 RBGE's Leigh Morris training OBG staff in the collection of vegetative propagation material on Jabal Al Akhdar (December 2006). Photo: Annette Patzelt.

Seeds were collected in a standard way (Fig. 3) into fabric bags and stored in boxes for transport. On longer field trips the seed drying process started in the field, usually by hanging the bags in shady and slightly breezy locations. The collection and propagation of vegetative material (cuttings and whole plants) proved more of a challenge in such a hot climate but, through collaboration with Royal Botanic Garden Edinburgh (RBGE) horticulturists, successful protocols were developed involving the correct selection of material (Fig. 4) and the use of moist sealable plastic bags and cool-boxes.

Fig. 5 Dr Annette Patzelt inputting collection data into the database in the field. Photo: Leigh Morris.

A fundamentally important part of the plant collection process was the gathering and recording of information on all the plants, including date of collection, name(s) of collectors, location (GPS coordinates; longitude, latitude and altitude), locality, type of material, life form, soil type, associated flora, local uses and descriptions. Voucher herbarium specimens, material for genetic analysis and photographs were also collected. The vouchers are stored in the OBG's herbarium. Temporary labels were used during transportation and much of the information was typed straight into the database on a lap-top computer in the field (Fig. 5). The database allows a link from the living collection to the herbarium voucher, to provide a back-up specimen should the living material fail for any reason.

PROPAGATION TECHNIQUES

After transport to the OBG nursery seeds were dried, cleaned and stored in the dark at room temperatures. Species from the high mountain areas in northern Oman were stored in a dark fridge at 10°C to provide stratification. A seed processing form was developed that remains with the seed lot from the moment it arrives in the garden until the seeds are sown. Prior to germination seeds are soaked in water for 24 hours and then directly sown into standard 200 × 300mm seed trays with potting media. Smaller seeds are broadcast into the trays but larger seeds are spaced using a template to form 40 holes in a tray. The seed trays are watered daily, being soaked in large trays, to enable water to penetrate from the bottom rather than from the top. The date of first germination is recorded. If germination occurs, young plantlets are pricked-out after reaching 50–100mm in height.

Fig. 6 RBGE's Nursery Supervisor, Peter Brownless, training OBG staff in vegetative propagation techniques. Photo: Annette Patzelt.

Initial attempts at rooting cuttings by the OBG team were variable, so RBGE staff were asked to visit Muscat in December 2006 in order to develop protocols for vegetative propagation (Fig. 6). Peat moss and vermiculite (ratio 1:1) was decided upon for the rooting media, the design of the propagation tunnels was modified to allow better access and OBG staff were taught the importance of looking after the cuttings and maintaining hygiene within a propagation environment.

It was believed to be important to start with less sophisticated methods of plant propagation, as the rented facilities were basic and there was not the depth of skill and experience within the OBG team. With the development of the staff and the move to new nursery facilities on the OBG site in June/July 2008, however, the propagation techniques and establishment and growth requirements will be expanded and, through experimentation, precise production protocols will be developed for every species.

Overall, propagation to date has been successful, with much learned that will be of use when the nursery expands into phase two. So far, 327 species from 68 different families have been propagated or collected, representing 29% of the country's flora (Table 1). Eighty-five of the species are on the National Red List (Patzelt, 2008). Appendix I summarizes the propagation success over the first two years. Initially, success rates were not recorded accurately and were counted as 'Very Poor' (success < 5%), 'Poor' (5–10%), 'Medium' (10–60%), 'Good' (60–80%) and 'Very Good' (> 80%).

Month	Total plants in nursery	No. of species	No. of families	No. of species on the Red List
February 2006	0	0	0	0
April 2006	2,021	102	40	23
June 2006	6,398	131	44	31
August 2006	9,267	165	54	42
October 2006	10,626	167	59	45
December 2006	16,563	244	59	49
February 2007	16,695	269	62	49
April 2007	26,038	288	65	66
June 2007	34,797	300	65	76
August 2007	35,866	303	65	76
October 2007	37,858	314	66	76
December 2007	38,296	317	67	77
February 2008	49,352	321	67	80
April 2008	50,658	321	67	80
June 2008	51,851	327	68	85

NB: The total flora of Oman contains c. 1,200 species within 124 plant families. 261 species are currently on the National Red List.

Table 1. Plant production and collection figures for the OBG nursery.

GROWING-ON PLANTS

After propagation, seedlings and rooted cuttings are potted-up and retained in a polythene tunnel until clear signs of root formation are obvious. They are then transferred into the larger polythene tunnel or shade structure. Whole plants, bulbs and tubers collected from the wild are treated in the same way.

RBGE staff worked with the OBG team in December 2006 to develop a standard OBG potting medium, consisting of peat moss, vermiculite and sweet soil (ratio 3:1:1) and slow release fertilizer. All plants were then placed in a cooled, shaded greenhouse, under a shade net providing 70% shade, and were watered daily. For succulents, plants of sand dunes and bulbs, however, different soil mixtures were developed by the OBG team: for succulents, coarse gravel and vermiculite (ratio of 1:1), for sand plants, sand plus the standard OBG mix (ratio 1:1) and for bulbs, the OBG standard mix plus coarse vermiculite and fine sweet soil is used (ratio of 1:2:1).

The propagation, growing and maintenance of so many different Omani plants from a range of restricted and extreme environments (and which have never been previously cultivated) has been a challenge and a huge learning curve for the OBG team but this has been helped greatly through the horticultural support, consultancy and the teaching of

Fig. 7 RBGE's Leigh Morris reviewing the growth of a batch of wild collected plants with OBG staff in the nursery at A Seeb. Photo: Annette Patzelt.

good maintenance and collection management techniques provided by Mark Richardson (BGCI), Dr Mike Maunder (Fairchild Tropical Botanic Garden) and the horticulturists from RBGE (Fig. 7). One of the key areas has been irrigation of plants from highly diverse habitats. The arid climate in Muscat, especially during the hot summer months, has increased the irrigation challenge and a couple of electrical power cuts have resulted in water supply failures that have damaged part of the collection.

PRODUCTION LIST

A key part of the plant collection and propagation for OBG has been the development of a detailed Nursery Production List, which lists the species and the size(s) and number required, for all the habitat areas. During the early collection and propagation of plants this list was basic but as more detailed habitat plans have been developed, the nursery team has been able to draw up a more accurate schedule with respect to numbers and types required. As with any nursery production list, however, it is still constantly evolving and will not be finalized until the OBG detailed design phase is complete.

The production list also serves as a reference for the landscape design team, as to which species are characteristic for which habitat. The use of the list as a tool during the first years of the planning and development allows for coordination between collection, cultivation and detailed design planning.

ACKNOWLEDGEMENTS

The Oman Botanic Garden is funded by the Diwan of Royal Court of the Government of the Sultanate of Oman. The authors are particularly grateful to Saif Al Hatmi, Shadia Al Rijeibi, Dareen Mehdi, Ghudaina Al Issai, Khalid Al Farsi and Zawan Al Qasabi (all Oman Botanic Garden) for their help and support. This work could not have been this successful without the hard work of the horticultural assistants, bravely surviving the summer nursery conditions of the garden's nursery rented facilities and their care of the plants. Special thanks are due to Mark Richardson (BGCI), Dr David Rae, Tony Miller, Sabina Knees and Peter Brownless (RBGE) and Dr Mike Maunder (Fairchild).
