Executive Summary

The Kazan Upland Natural Subregion occurs in the far northeastern corner of Alberta and occupies 1.5% of the province (Natural Regions Committee 2006). The main area lies north of Lake Athabasca. It is bordered on the east and north by the Alberta–Saskatchewan and Alberta–Northwest Territories boundaries, respectively, on the west by the Slave River, and on the south by Lake Athabasca. There is a small outlier east of the Athabasca River between Fort McMurray and Fort Chipewyan embedded within the Athabasca Plain Natural Subregion. Elevations range from about 150 m to over 400 m. Approximately 60% of the landscape of the Kazan Upland subregion is exposed precambrian bedrock (Natural Regions Committee 2006).

This guide represents the analysis of 73 plots described in the Kazan Upland subregion. The 73 plots represent 34 community types. These types are split into: A. Native grasslands 8 community types B. Native shrublands 4 community types C. Deciduous types 8 community types D. Mixedwood types 4 community types E. Conifer types 10 community types. The dominant plant species, canopy cover, soil and environmental conditions are outlined for each type.

Acknowledgements

Landscape classification is the process of breaking the landscape into definable and manageable pieces through a hierarchical classification. In the early 1990's the forested landscape of Alberta was classified using a well organized hierarchical system (Archibald/ Beckingham / Klappstein). Unfortunately this left about 50% of the remaining natural landscapes of the province unclassified. Starting in the late 1990's rangelands undertook efforts to classify the rangelands of Alberta. A need for consistency across the province was recognized. Therefore a hierarchical classification that built on the forested classification was used for all forest dominated subregions in the province.

These classifications involve taking large amounts of vegetation, soils and landscape inventory data taken from the ECOSYS database and compiling the data into succinct descriptive summaries for each ecological site, ecological site phase and plant community within a subregion.

In 2010 funding was provided by Policy and Planning Division, Alberta Environment and Parks in order to produce hard copy pdf documents from the ECOSYS website.

Introduction and Background

The province of Alberta is covered by a broad spectrum of vegetation regions from prairie in the South, to alpine vegetation in the mountains and dense forests and extensive wetlands in the Central and Northern parts of the province. These broad vegetation regions have been classified into 6 natural regions and 21 subregions for the province (Natural Regions and Subregions of Alberta 2006). Each of the regions consists of groups of plant communities which are influenced by environmental conditions and human impacts. Intensive management of these regions requires the ability to recognize the vegetative communities that have similar productivities and respond to disturbance in the same way. These ecological classification guides are highly regarded by most resource managers as a tool which may assist in decision making processes related to livestock grazing, prime habitat for wildlife, productive watersheds and recreational areas, addressing biodiversity and conservation matters and numerous other potential related topics.

The purpose of this guide was to develop a framework that would easily group the ecological sites and vegetative community types in the Kazan Upland Natural Subregion of the province. Ecological site classification helps to organize our current understanding about ecosystem function. This organization is achieved by grouping research plots into similar and functional units that respond to disturbance in a similar and predictable manner.

The ecological site classification system outlined in this document organizes ecological information into a format that facilitates understanding and provides a structure for ecologically based management. The system has been developed primarily as a field tool to complement the user's knowledge about ecological site classification, soil description, and plant identification. The objectives of the ecological site classification are to provide a consistent overview of the common vegetation communities and site characteristics in order to:

1. to facilitate the application of ecological information to decisions on a wide variety of activities within the realm of land resource management
2. to facilitate the collection and organization of information to expedite the development of resource management applications and decision support systems
3. to promote communication among resource managers and between managers and the public
4. to provide a common basis for integrated planning, and
5. to reduce resource management costs by integrating ecological information into the decision-making process.

This guide builds on the work outlined in the Field guide to Ecosites of Northern Alberta (Beckingham and Archibald 1996) for the Canadian Shield Natural Region. In 2006 (Natural Regions and Subregions of Alberta 2006) the original Canadian shield region was split into the Athabasca Plain and Kazan Upland subregions. This guide outlines the analysis of 73 plots described in the Kazan Upland subregion.

Physiography, Climate and Soils

Please note this summary of Natural Subregion characteristics is extracted directly from the Natural Subregions guide (Natural Regions Committee 2006) and is presented here for the reader's convenience.

The Kazan Upland Natural Subregion is 9719 km2, covering only 1.5% of the province. It features short, warm summers where July is the warmest month, but possesses the coldest winters of any Natural Subregion in Alberta due to continental polar and continental arctic weather systems. July is also the month of maximum precipitation. Winter snowfall accounts for 40% of the annual total (Natural Regions Committee 2006). The Alberta Climate Model indicates the Kazan Upland Natural Subregion receives about the same annual precipitation as the Dry Mixedgrass Natural Subregion, and has a potential summer moisture deficit (summer moisture index) comparable to that of the Northern Fescue Natural Subregion. Figure 4-6.1 and Table 3-2 in Natural Regions and Subregions guide of Alberta provides monthly and annual climate data summaries. The prevalence of rock barrens and well to rapidly drained glacial deposits, together with low rainfalls, produce conditions that are favorable for non-vascular and vascular plants that are adapted to dry conditions.

Extensive outcrops of Precambrian bedrock, composed of Aphebian and Archaen granitoids define the Kazan Upland subregion. The westernmost edge of the Canadian Shield, defines the limits of the Kazan Upland; approximately, 60 percent of the landscape is exposed bedrock. The surficial landscape is comprised of about 45 percent glacially scoured rock, about 40 percent sandy and gravelly ice-contact glacial drift, and about 15 percent organic accumulations in low-lying areas. Parent materials are ice-scoured bedrock and coarse textured glacial.

The terrain is hummocky to rolling with relief up to 50 m. Nonsoils occur across about half the area. Surficial deposits between bedrock outcrops are mainly coarse and acidic. Soils on these materials are predominantly eluviated Dystric Brunisols with associated Orthic, Gleyed and Lithic Subgroups, the latter on very thin deposits over bedrock. Wetlands are a complex of Typic and Fibric Mesisols, many with Terric Subgroups, Peaty Gleysols also occur (Natural Regions Committee 2006).

Approach and Methods of Classification

Approach:

Ecological classification hierarchy and terminology

The system of classification in this guide was initially based on the community type approach of Mueggler (1988). Mueggler's system was chosen over the habitat type approach (Daubenmire 1952) or ecosystem association approach (Corns and Annas 1986) because it could classify plant communities irregardless of their successional status. However, as the philosophy of proper functioning condition of a site evolved, it became apparent (through data analysis) that there was a need to also organize the various plant communities based on their response to disturbance (i.e. disturbance vs. natural succession) within an area under similar environmental influences.

It was determined that the ecosystem classification system developed by Corns and Annas (1986) and Beckingham et al. (1996) could accommodate this additional requirement. Thus, this classification system is a combination of Mueggler (1988) and Beckingham et al. (1996). Consequently, this guide adopts a similar ecological unit classification hierarchy (ecodistrict, ecosection, ecological site, ecological site phase, plant community). The ecological classification system is nested within Alberta's geographically based natural region and subregion classification system (Natural Regions Committee 2006).

Ecodistrict

The ecodistrict level is a unique pattern of slope, landform, soils and vegetation. Mapping of this unit is usually done at a scale of 1:1,000,000 to 1: 250,000 within the whole province (Strong and Anderson 1980). This level of the classification hierarchy is spatially defined and may or may not be unique to a subregion.

Ecosection

The natural subregion used by the Alberta Government is equivalent to the ecoregion defined by the Canada Committee on Ecological Land Classification (CCELC) as part of a multi-level national mapping system for Canada and that was used for integrated resource planning in Alberta (Marshall et al. 1996). Similarly, the ecodistrict as presently used and its associated scale of mapping is equivalent to the ecodistrict defined by the CCELC. However, the ecosection has a somewhat different meaning in the current context than it did in the national system or than it did when it was applied to integrated planning maps in Alberta in the 1980's and 1990's. For those mapping projects, the ecosection was a subdivision of the ecodistrict and was mapped at 1:20 000 to 1:50 000 as a more specific delineation of recurring landform and vegetation patterns, usually with reference to major community type groups or soil subgroups. In the current scheme, the ecosection is a term used to define one ecodistrict or an aggregation of ecodistricts that represent one or more climatic variants within a natural subregion; therefore, its mapping scale is flexible. This level of the classification system is not spatially defined. The ecosection is a unique pattern of slope, landform, soils and vegetation and may also represent a slight change in the climate of a subregion. Mapping of this unit is usually done at a scale of 1:1,000,000 to 1:100,000 and can be a grouping of ecodistricts or at smaller scales outliers in a subregion. For example the Lower Boreal Highlands subregion is split into the foothills and boreal ecosections which are influenced by their proximity and location within the Boreal and Foothills Natural Regions. Spatially these two ecosections are split by grouping ecodistricts. In contrast an example of a smaller scale ecosection (1:100,000) is the Cypress Hills outlier of the Montane subregion. Subregion ecosections have a characteristic sequence of ecological sites according to soil moisture regime (SMR) and, to a lesser degree, soil nutrient regime (SNR). Currently there is no ecosection described for this subregion.

Ecological Site

Ecological sites are ecological units that develop under similar environmental influences (climate, moisture, nutrient regime). They are groups of one or more ecological site phases that occur within the same portion of

the edatope (moisture/nutrient grid). Each ecological site is designated with a small letter. These letters range from "a" the driest ecological site and the last letter being the wettest. Each ecological site has been given a name that conveys some information about the ecology of the unit. Ecological sites are typically named after plant species that are common or typical of the site (eg. e low-bush cranberry). The plant that the ecological site is named after, however, may not be present in every plot or stand belonging to the site. Ecological site in this classification system, is a functional unit defined by moisture and nutrients. It is based on the combined interaction of biophysical factors which together dictate the availability of moisture and nutrients for plant growth. Thus, different ecological sites vary in their moisture and nutrient regime and have similar characteristic plants and soils.

Ecological site phase

An ecological site phase is a subdivision of the ecological site based on the dominant species in the canopy. On lowland, meadow or grassland sites where tree canopy is not present the tallest structural vegetation layer with greater than 5% cover determines the ecological site phase. Generally, ecological site phases are mappable units and spatial ecological site phase land cover datasets have been developed from AVI (Alberta Vegetation Inventory) (Derived Ecosite Phase (DEP)) and PLVI (Primary Land Vegetation Inventory). Ecological site phases are identified by the ecological site letter "a" along with a number "a1" representing the phase within the ecological site. Ecological site phases have a distinct range in canopy composition, lower strata plant species and pedogenic processes. The ecological site phase has a strong ecological basis and correlates well with forest cover on forest inventory maps.

Plant community type

Ecological site phases may be subdivided into plant community types, which are the lowest taxonomic unit in the classification system. While plant community types of the same ecological site phase share vegetational similarities they differ in their understory species composition and abundance. Generally the plant community types are named by combining the name of the dominant plant species in each structural layer (eg. White spruce/Horsetail/Moss)

Methods:

Plant community classification

Data used to create this guide were collected from field plots within the Kazan Upland subregion. Seventy three plots were used to create the classification for this subregion. Field inventory for these plots generally followed the Ecological Land Survey Site Description Manual (2003) and uses various site, vegetation and soils forms. Plot data was analyzed using the multivariate analysis techniques of classification and ordination. Classification is the assignment of plots to classes or groups based on the similarity of species within each plot. A polythetic agglomerative approach was used to group the samples. This technique assigns each plot to a cluster which has a single measure. It then agglomerates these clusters into a hierarchy of larger and larger clusters until finally a single cluster contains all the plots (Gauch 1982). The cluster analysis was performed in SAS with Euclidean distance used as the Cluster Distance Measure and Ward's method was used in the Group Linkage Method. The groupings generated in cluster analysis were overlain on the site ordination to determine final groupings.

Ordination was used to find relationships among species, communities and environmental variables. Ordination reduces the dimensionality of the data to 1-3 most important axes to which environmental gradients can be assigned. The ordination technique used in the analysis of the data was DECORANA (Detrended Correspondence Analysis). Once final groupings were determined on the ordination specific environmental variables can be assigned to the variation outlined on the ordination axes.

Plant community summaries were generated by averaging plant species composition, range in composition, and percent constancy of occurrence, among vegetation inventory plots which were part of a community type. Environmental data was sorted into the same plant community groupings to create the plant community descriptions outlined in this guide. The number of sample plots on which the description was based is also

provided (e.g. n=16).

Ecological Health and Ecological Status Score

Ecological health is determined by comparing the functioning of ecological processes on an area (e.g. plant community polygon) of to a standard (i.e. Reference Plant Community) described within an ecological site description. An ecological site is defined by the Task Group on Unity and Concepts (1995) as, “a distinctive kind of land with specific physical characteristics that differs from other kinds of land in its in its ability to produce a distinctive kind and amount of vegetation”. This guide can be used to determine the appropriate reference plant community, within an ecological site, for a health assessment. We use health terminology (healthy, healthy with problems, or unhealthy), to rank the ability of the land to perform certain ecological functions. These functions include: net primary production, maintenance of soil/site stability, capture and beneficial release of water, nutrient and energy cycling and plant species functional diversity. For a detailed description on how to assess health for various plant communities please refer to “Rangeland Health Assessment for Grassland, Forest and Tame Pasture” (Adams et al. 2009).

An ecological status score (i.e. the integrity of the plant community composition compared to the reference plant community) has been added to each community type description. These values are based on what is currently known about how a reference plant community (RPC) responds to various kinds and levels of disturbance or successional processes. The values indicate how a particular plant community fits in the state and transition model relative to the RPC. If an experienced observer wishes to estimate the health of a plant community without completing a health form, (e.g. a small riparian area), these values can be used as a guide. Occasionally there are 2 options provided for the ecological status score. This was done for two reasons: 1) to express the range of divergence from the RPC possible for a particular plant community; or 2) to allow for different health forms to be used in communities with variable shrub or tree cover (e.g. on sites with high woody cover and/or an obvious LFH layer use the forest rangeland health form and the corresponding ecological status score; on sites dominated by herbaceous cover and/or an obvious herbaceous litter layer use the native grassland form). Late seral plant communities tend to be superior in the efficient capture of solar energy, in cycling of organic matter and nutrients, in retaining moisture, in supporting wildlife habitat values and in providing the highest potential productivity for the site (Adams et al. 2009). In contrast, early seral disturbed stages ability to produce a distinctive kind and amount of vegetation”represent plant communities with diminished ecological processes, which are less stable and more vulnerable to erosion and invasion by weeds and non-native species. In most cases these late seral plant communities are used as the RPC, but sometimes management goals influence the choice of RPC (e.g. a cut block to be maintained as untimbered rangeland).

Correlation of Soils and Ecological Sites

Please note this summary of Natural Subregion characteristics is extracted directly from the Natural Subregions guide (Natural Regions Committee 2006) and is presented here for the reader's convenience.

The acidic characteristics of granitic bedrock exposures, the well to rapidly drained glacial drift, and frequent fires significantly impact the vegetation in this subregion. Communities are associated with dry rock barrens are widespread, and although species diversity is low in any given locale, the variety of habitat results in high species variety across the barrens. Various lichen communities occupy south-facing and steep rock faces and slopes--many found only in the Kazan Upland (Natural Regions Committee 2006). "Pocket" communities grow in rock crevices and sheltered locations where mineral soil has accumulated and moisture conditions are right. The species associated with these types of areas are stunted jack pine and Alaska birch forming open stands, with a sparse understory of bearberry, ground juniper, bog cranberry, and a variety of drought-tolerant ferns and other herbs, mosses, and lichens (Natural Regions Committee 2006).

Places with course textured, rapidly drained and dry sandy or gravelly soils support more vigorous pine growth. The driest sites are vegetated by open jack pine stands with a patchy carpet of lichens below. Moister sites support more diverse understories of green alder, common blueberry, bearberry, common Labrador tea, Canada buffaloberry, bunchberry, and other herbs and feathermosses. Aspen, Alaska birch, and black spruce are locally common in places.

Small lakes occupy about 10% of the Kazan Upland Natural Subregion, and wetlands are common in the lower relief western half, covering approximately 20%. Adjacent to these areas, communities of moister adapted species can develop. These include aspen, balsam poplar, Alaska birch, white spruce, and a diverse shrub and forb understory. Bog communites are the dominant wetland type. Black spruce forms open-to-dense stands with an understory of common Labrador tea, leatherleaf, bog cranberry, cloudberry, and peat moss on Organic soils. Permafrost is discontinuous but widespread. Nutrient rich wetlands typically have open forests of tamarack, willow, dwarf birch, sedges, and rich-site mosses.

Nonsoils (e.g., bedrock outcrops) occur across about half the area. Surficial deposits between bedrock outcrops are mainly coarse and acidic. Soils on these materials are predominantly eluviated Dystric Brunisols with associated Orthic, Gleyed and Lithic Subgroups, the latter on very thin deposits over bedrock. Wetlands are a complex of Typic and Fibric Mesisols, many with Terric Subgroups. Peaty Gleysols also occur. Appendix 7 summarizes the proportional occurrence of soil types in the Kazan Upland Natural Subregion (Natural Regions Committee 2006).

Guidelines for Determining Ecological Sites

Alberta currently uses two ecological classification methods to determine ecological sites. In the agricultural settlement area of the Province, resource managers can determine site soil conditions using AGRASID (Agricultural Region of Alberta Soil Inventory Database). In the Rocky Mountain, Foothills and Boreal Natural Regions, the Ecological Landscape Classification approach incorporates both vegetation and site conditions (climate, soils and geology) into a hierarchical ecological unit classification (e.g. subregion, ecodistrict, ecosection, ecological site, ecological site phase, plant community) (Strong and Thompson 1995). Ecological sites are areas of similar climate, moisture and nutrient regimes. The combination of moisture and nutrient regimes can be represented on a two-dimensional grid called the edatope grid. The edatope grid is a two-dimensional table with soil moisture regime increasing from bottom to top along the vertical axis and soil nutrient regime increasing from left to right on the horizontal axis. Soil moisture regime (SMR) is defined as the average amount of soil water available annually for evapotranspiration by vascular plants (Meidinger and Pojar 1991). The SMR uses nine classes to define the available soil moisture, which range from the driest (very xeric) to the wettest (hydric). Soil nutrient regime (SNR) is defined as the amount of essential soil nutrients that are available to vascular plants over a period of several years (Meidinger and Pojar 1991). SNR is broken down into five classes that range from A (very poor) to E (very rich). Generally ecological sites are named from low moisture/low nutrient to high moisture/high nutrient. Ecological sites within a Natural subregion are defined unique combinations of soil moisture and nutrients. These conditions, in addition to climate, terrain, and elevations create conditions favourable to specific suite of plants referred to as Indicator species. For example a site with a subxeric moisture regime and poor nutrient regime site is characterized by the "a" [bearberry (subxeric/poor)] ecological site. A resource manager can review the indicator plant species of the ecological site, plant community types, soils and site conditions to see if the plant community in question fits the general descriptions. The following steps provide a framework for determining ecological sites.

Step 1 Review background information and pre-stratify the area to be classified

Review information about the area of interest to learn what you can about the landscape and ecology. Consult the natural subregions and Derived Ecosite Phase (DEP) or Primary Land Vegetation Inventory (PLVI) maps to ensure you are using the correct subregion guide. DEP and PLVI classification will also give you the common ecological site phase for a particular forest polygon.

Step 2 Carry out a quick reconnaissance of the site to be classified

Take note of the variability and relationship between topography and position on the landscape and the general plant species distribution including trees and understory. Check the DEP and PLVI ecological site phase maps.

Step 3 Choose a location that appears to be representative of the area to be classified

Locate an area for your assessment that appears to be representative of the site to be classified, and is homogeneous in slope, plant cover, and overstory canopy conditions as possible. Avoid locating the sample in areas that have received significant natural or artificial disturbance. Also avoid ecotone areas or relatively small areas that are transitional between homogenous ecological units such as slope breaks.

Step 4 Determine the plant species composition and abundance

Determine the plant species composition and abundance within a 10x10 m plot. Also record any species that appear to be representative of the ecological unit but occur outside the plot within the same slope position and on the same parent materials. Abundance is estimated by determining the amount of ground area that is covered by the plant species when its canopy is projected onto the ground surface (Ecological Land Survey Site Description Manual 2003).

Step 5 Determine the important soil properties

To collect soils data, a soil pit must be dug or augered. In most cases a soil pit 60 cm deep will be adequate. A deeper pit is required when the soil has a coarse to moderately coarse texture. In these cases the pit is dug deeper to see if there are finer-textured layers that are influencing ecological function below the 60 cm of coarse material. A deeper pit is also required when the plant community on the site cannot be explained by the site conditions and soil conditions above 60 cm. The minimum soils data that should be collected within a plot to classify it correctly are organic matter thickness, humus form, Ah horizon thickness, surface texture, effective texture, presence of seepage, depth to mottles, depth to gley, coarse fragment content, parent material/landform and drainage.

Step 6 Determine important site properties

Important site variables that should be collected include topographic position, slope, aspect, moisture regime, and nutrient regime.

Step 7 Determine the natural subregion, ecological site, ecological site phase and plant community type.

There are several ways to determine the ecological site, ecological site phase and plant community type. The first way is to assign an ecological classification to a site is to use the field data collected and go through the various subregion guides to identify the ecological site. You can also use the dichotomous keys to ecological site and ecological site phase. Once you find a potentially correct plant community type, check the soil, site and vegetational characteristics of your site to make sure it matches the ecological site, ecological site phase and plant community type on the various fact sheets. To consider all ecological site choices, you must compare the characteristics of your site, with the descriptions on the fact sheets for all ellipses that overlap the moisture and nutrient classes of your site on the edatope grid for the subregion and adjacent subregions within the area (Ecological Land Survey Site Description Manual 2003).

How to use the Guide

Organization of the guide

This guide is an expansion of the Ecosites of Northern Alberta guide (Beckingham and Archibald 1996). It contains new information and it is recommended that the reader has access to relevant information from both guides. The community types in this guide are closely related to the ecosites and ecosite phases outlined in Ecosites of Northern Alberta (Beckingham and Archibald 1996), and are similarly arranged (e.g. Table 1). Table 1 is a reproduction of Figure 20 in Ecosites of Northern Alberta with community types in this guide further separated into reference range plant communities, successional communities and harvesting and fire communities. The "Successional community types" or "Harvesting and Fire succession" categories outline the successional sequence the community types undergo with heavy grazing pressure, harvesting or fire disturbance.

The bulk of this guide consists of ecological sites, ecological site phase and vegetation community descriptions which include information on the dominant plant species, canopy cover and environmental conditions. Where available, plant community successional information (ie response to grazing) has been included to help you determine rangeland health and the successional relationships of an ecological site.

Ecological units within a subregion are classified by their position on the edatopic grid.

The information in this guide is presented and named by:
1. Subregion/Ecological area
a. Kazan Upland (KU)
2. Dominant cover type
a. A-grassland
b. B-shrubland
c. C-deciduous
d. D-mixedwood
e. E-conifer
3. A number- Generally, communities are named/numbered from low moisture /nutrient status to high moisture/nutrient status. For example, KUE1 Pj/Lichen community on the"b" subxeric/poor ecological site, while KUE10 Lt/Alder/Sedge community type on the "j" subhydric/rich ecological site.

Eg. KUE1 Pj/Lichen

NOTE: As additional information is collected and new ecological units are identified and described, an attempt is made to fit them into the pre-existing ones.

How to read the fact sheets

The field guide contains 4 types of fact sheets: One for ecosection, one for ecological site, one for ecological site phase and one for plant community type.

Ecosection

There is an identification code at the top of the ecosection fact sheet and a name followed by the number of sample sites (pg 20). Each ecosection has been given a name that conveys information about the location of the unit and are frequently named after a general location within the subregion (Ecosection: Cypress Hills (Mc) of the Montane subregion). A short text description of the site is given under the General Description (pg 20), this is followed by a picture or a cross section diagram and map of the ecosection(pg 20). The section on successional relationships gives a brief note about the spatial locations and differences in ecosections (pg

20). This is followed by a list of envrionmental variables (elevation), ecodistricts and ecological sites associated with the ecosection (pg 20).

Ecological site

There is an identification letter at the top of the ecological site fact sheet and a name, moisture and nutrients followed by the number of sample sites (pg 21). Each ecological site has been given a name that conveys information about the ecology of the unit and are frequently named after a common plant species. A short text description of the site is given under the General Description (pg 21), this is followed by a picture or a cross section diagram of the ecological site (pg 21). The section on successional relationships gives a brief note about the temporal development of the ecological site (pg 21). It generally describes the successional relationships among the ecological site phases and plant community types. Plant species that are indicators of the ecological conditions on the site are listed (pg 21). Site index at 50 years of age at breast height (1.3 m) is presented next. The mean site index is presented in meters followed by the standard error and the number of trees used to calculate the mean (pg 21). Environment and soil variables are then listed and represent a roll-up from the plant community and ecological site phase descriptions (pg 21). Variables that represent environment and soils have a number (1) that indicates the number of the samples in which each variable class occurred. Data has been collected and analyzed from many sources over 40 years and data gaps may exist for many variables. The frequency of occurrence value indicates the number of sampled plots for which data was collected for that variable at the Ecological site, Ecological site phase and plant community fact sheets. Optional variables such as soil exposure, LFH thickness, forage production and stocking rate for livestock may also be listed and represent a roll-up for the plant community and ecological site phase.

Ecological site phase

There is an identification code at the top of the ecological site phase fact sheet and a name followed by the number of sample sites (pg 22). Each ecological site phase has been given a name that conveys information about the dominant tree species or lifeform (shrubland, grassland, tame/disturbance) of the unit and are frequently named after a common plant species. A short text description of the site and successional information maybe given under the General Description or Successional relationships (pg 22) if it is provides more detail than is available on the ecological site fact sheet. Plant species that are indicators of the ecological conditions on the site are listed with the average cover summarized from the various plant communities (pg 22). Indicator species for the ecological site phase are identified with an asterix "*" and are rolled-up to develop the indicator species list for the ecological site fact sheet. Environment and soil variables are then listed and represent a roll-up from the plant community (pg 22). Optional variables such as soil exposure, LFH thickness, forage production and stocking rate for livestock may also be listed and represent a roll-up for the plant communities.

Plant community

There is an identification code at the top of the plant community fact sheet and a name followed by the number of sample sites (pg 23). The name of the plant community is generally the common name of the indicator plant species within the various lifeform layers (tree, shrub, forb, grass, lichen, moss). This is followed by the latin name of each indicator species and a general description of the community type describing its unique ecology. Plant species that are indicators of the ecological conditions on the site are listed with the mean cover summarized, range in cover and overall constancy (frequency of plots that the species was described (pg 23)). Environment and soil variables are then listed and represent a roll-up from the various plots and assessements (pg 23). Optional variables such as soil exposure, LFH thickness, forage production and stocking rate for livestock may also be listed and represent a roll-up for various plots.

Results

This guide represents the analysis of 73 grassland/lichen, shrubland, conifer and deciduous field plots described from the Kazan Upland subregion. These plots are distributed between 34 community types:

A. Native grasslands 8 types
B. Shrubland 4 types
C. Deciduous 8 types
D. Mixedwood 4 types
E. Conifer 10 types

The dominant plant species, canopy cover and environmental conditions are outlined for each community type.

General Ecological Descriptions

Please note this summary of Natural Subregion characteristics is largely extracted directly from the Natural Subregions guide (Natural Regions Committee 2006) and is presented here for the reader's convenience.

Forest Communities

Vegetation in the Kazan Upland Natural Subregion is strongly influenced by the distribution and acidic characteristics of granitic bedrock exposures and well to rapidly drained glacial drift, and by frequent fires. Beckingham and Archibald (1996) produced a general description of vegetation communities based on limited plot data. Coarse textured, rapidly drained and dry sandy or gravelly soils support vigorous jack pine growth. The driest sites are vegetated by open jack pine stands with a patchy carpet of lichens on the forest floor. Moister sites with submesic-mesic moisture regimes support more diverse understories of green alder, common blueberry, bearberry, common Labrador tea, Canada buffaloberry, bunchberry, other herbs and feathermosses with an overstory of jack pine, white spruce or aspen. Aspen, Alaska birch and black spruce are locally common in places. Brunisols are common soils on these upland forested community types. On moister sites with subhygric to hygric moisture regimes communities of aspen, balsam poplar, Alaska birch, white spruce and a diverse and lush shrub (red osier dogwood and willow on rich sites and Labrador tea on poorer sites) and forb (horsetail) understories develop in bands adjacent to wetlands and along lakes.

Wetlands

The Alberta Wetland Classification System (2015) recognizes the hydrological, biogeochemical and biotic processes that affect differing characteristics that can be used to define a wetland. The AWCS recognizes five classes of wetlands in Alberta: bogs, fens, marshes, shallow open water and swamps. Wetlands can be divided into two broad groups: **peatlands** and **mineral wetlands**. In general the AWCS considers bogs and fens to be peatlands and all other wetland classes (i.e. swamps, marshes and shallow open waters) are considered to be mineral wetlands. For the most part the ecological sites align with AWCS five classes of wetlands (Table A), however some willow, bog birch, sedge, marsh reedgrass and tufted hairgrass dominated ecological sites because of their moisture regime and species composition are classified as meadows and fens and have mineral soils but in the AWCS classification these sites are mineral wetlands which are considered marshes or swamps.

Table A. Cross walk of broad AWCS classes to general Ecological site

AWCS	Ecological Sites
Bog	Bog
Fen	Poor fen (Organic soils)
Fen	Rich fen (Organic soils)
Marsh	Poor fen, Rich fen (Mineral soils)
Marsh	Meadows
Marsh	Marsh
Swamp	Red osier dogwood, Honeysuckle, Horsetail and wetter Labrador tea, black spruce dominated ecological sites.

Dozens of small lakes occupy about 10 percent of the Kazan Upland Natural Subregion, the largest being Cornwall, Colin, Charles, Wylie and Andrew Lakes. A few small streams drain into the Slave River. Wetlands are most common in the lower relief western half of the Natural Subregion, and cover about 20 percent of the total area. Treed poor fens and bogs on Organic soils are the most common wetland type. Shrubby fens and marshes on Organic and wet mineral soils also occur.

Bog communities are the dominant wetland type. Black spruce forms open-to-dense stands with an understory of common Labrador tea, leatherleaf, bog cranberry, cloudberry and peat moss on Organic soils. Permafrost is discontinuous but widespread. Nutrient-rich wetlands typically have open forests of tamarack, willow, dwarf

birch, sedges and rich-site mosses. Marshes can be locally extensive in sheltered lake bays or along creek channels, and are dominated by water and small bottle sedge, bulrushes, and in deeper water, pondweeds.

Grasslands

Upland dry grasslands are not common in the Kazan Upland subregion. Allen et al. 2004 did observe a hay sedge dominated community on upper to mid slope positions on steep south and west facing slopes with sandy or gravelly glacial deposits in the Colin-Cornwall Lakes Wildland Provincial Park. Saline meadow complexes were described within the La Butte Creek Wildland Provincial Park (Allen et al. 2002) at two sites. Site 1 which is described was slightly drier than site 2 and was dominated by mat muhly, shooting star and seaside arrow grass. The other site which was slightly wetter was dominated by brown moss, awned sedge and seaside arrowgrass on the drier margins. It was felt that the mat muhly dominated community was subjected to higher levels of salt through evaporation. Raup (1935) described similar saline complexes in Wood Buffalo National Park and Bailey et al. (1992) described saline complexes in the Yukon Territory. The wettest edges were dominated by samphire sea blight, the Nuttall's saltgrass, foxtail barley and reedgrass and willow communities on the drier edges.

Lowland sites dominated by water sedge and marsh reedgrass were also observed in the Colin-Cornwall Lakes Wildland Park (Allen et al. 2004). The marsh reedgrass community was observed in patches or in narrow bands besides lakes, rivers and streams. They also observed fairly extensive meadows of marsh reedgrass near ponds and lakes. Water sedge and beaked sedge communities were observed along the edges of small ponds or a linear community along drainages where moisture was sufficient. Marshes dominated by cattails tend to occur in small patches along creeks (Allen et al. 2004).

Shrublands

Upland shrub types develop when soil conditions are too poor for tree growth or tree canopy has been removed mechanically or by fire. On eroded glaciofluvial kames a Bearberry/Indian ricegrass community was described (Allen et al. 2002). Allen et al. (2004) found this community type graded into open jack pine stands in La Butte Creek Wildland Provincial Park. Upland forest sites disturbed by fire will often have a early successional shrub phase. Labrador tea, lichen and feather moss tend to dominate the poorer sites and rose, Saskatoon, green alder and Bebb's willow the more mesic sites. Shrub communities dominated by willow, water birch and bog birch dominate the moister and richer sites. Sedges and reed grasses (Calamagrostis spp) dominate the drier edges of marshes or areas that have standing water only during spring runoff (i.e. fens). Willow will invade into these fens to form the Willow/Sedge and Willow/Reed grass plant communities and bog birch and Labrador tea tend to dominate the poorer nutrient sites.

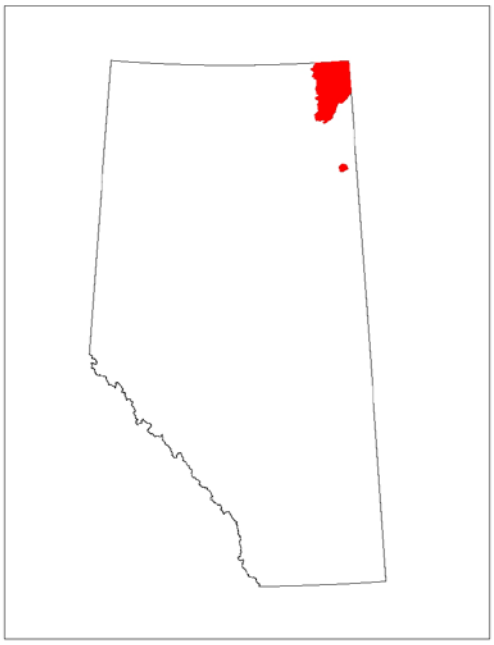
KU Kazan Upland (n=73)

Natural Subregion: Kazan Upland

General Description

This subregion has not been split into ecosections. It includes the Uranium City and Hart Lake Plain ecodistricts. The subregion is located north of Lake Athabasca in the Northeastern part of the province with a small outlier at the headwaters of the Marguerite River. It is bordered by Athabasca Plain in the south and Northern Mixedwood and Peace Athabasca Delta subregions on its eastern boundary.



Environmental Variables

a lichen stone fields (n=1)

Natural Subregion: Kazan Upland

Ecosection: KU Kazan Upland

General Description

This ecosite occurs on xeric rocky outcrops throughout the Kazan Upland subregion. Moisture and nutrients are virtually nonexistent on these rock outcrops, where nearly 60% of the landscape in the subregion is exposed bedrock. Where there is some moisture accumulation in the rock crevices Cladina species and some grasses, sedges and xeric forb species are found growing. These sites also have high potential for extreme exposure to wind and insolation. There is very little soil or organic material present; therefore, the lichens have to rely on the rock substrate and the air for their moisture and nutrient requirements. Only lichen appears to tolerate the existent conditions on these rocky outcrops.

KUA1 Lichen stonefield (n=1)

(Umblicaria spp.)

This community type represents the lichen cover on rock outcrops throughout the subregion. These Precambrian rock outcrops represent 60% of the landscape in the subregion (Natural Regions Committee 2006)). There are no soil or organic material associated with the exposed bedrock which favours the growth of crustose lichens. In the rock crevices where some organic matter and moisture accumulates reindeer lichen is common.

aa Sand heather/moss (xeric/poor) (n=0)

Natural Subregion: Kazan Upland

Ecosection: KU Kazan Upland

General Description

This ecological site represents the sand of paleodunes of various types, including parabolic and longitudinal dunes and is more common in the southern outlier of the Kazan Upland and Athabasca Plain subregions. This ecological site is primarily made up of large, distinctive dune ridges that rise well above the surrounding wetlands or sand plains. The dunes characteristically have steep slopes, dune crests and often include areas of active sand(blowouts).Tops of stabilized dune ridges have mature jack pine / lichen communities. Blowouts are generally unvegetated, with areas of sand heather / lichen crust beginning the stabilization process. Jack pine / green alder communities can be found in moister locations (e.g. bases of sand ridges). This ecological site is not common in the Kazan Upland subregion and currently no data has been collected.

Organic Thickness:

Parent Material:

Humus Form

LFH Thickness	Mean	Min	Max	Count
cm:	0.00	0.00	0.00	0

Successional Relationships

Due to the dry nature of the site often only sand heather and lichen will dominate the site. Jack pine and alder will invade in the moister areas or on northerly aspects where the dunes have stablized. See the Athabasca Plain subregion guide for a complete description of this ecological site.

Indicator Species

aa1 grass/Sand heather (n=0)

Natural Subregion: Kazan Upland
Ecosection: KU Kazan Upland

Ecosite: aa Sand heather/moss (xeric/poor)

General Description

A number of ecological site phases currently have no data. These ecological site phases have been created as place holders because they were described in adjacent subregions (Athabasca Plain). This ecosite phase is more common in the southern outlier of the Kazan Upland subregion. See the Athabasca Plain subregion guide for a description of the plant communities.

b bearberry/lichen(subxeric/poor) (n=18)

Natural Subregion: Kazan Upland

Ecosection: KU Kazan Upland

General Description

This ecosite has dry conditions with rapidly drained acidic soils and poor nutrient status due to the coarse-textured glacial parent materials. These sites commonly have bedrock within 1m of the surface. Plants that are indicative of the nutrient-poor substrate include bearberry, lichen, bog cranberry, and blueberry. Open-canopied jack pine stands dominate this ecosite that commonly has a carpet of lichens covering the forest floor. The picture of this ecosite is for the bearberry/lichen shrub phase (b2) of this ecological site.

Successional Relationships

Due to the dry nature of this ecosite, succession to a black spruce canopy is slower than the fire return interval. Pine is maintained for relatively long periods from colonization of the site after fire to the climax stages. The pine phase of this ecosite can be considered a fire edaphic climax.

KUE1 Pj/Lichen (n=9)

(Pinus banksiana/Cladonia spp.)

This community type is found on very dry sandy or gravelly sites that are rapidly drained. Stunted jack pine and Alaska birch form open pocket communities with a sparse understory of bearberry, juniper and lichen in rock crevices or sheltered locations where mineral soil has accumulated (Natural Regions Committee 2006). Where the soil is better developed vigourous jack pine growth is evident. As the moisture increases the understory often becomes dominated by blueberry.

KUE2 Pj/Bearberry (n=6)

(Pinus banksiana/Arctostaphylos uva-ursi)

This community type is very similar to the jack pine/lichen community type that was previously described but appears to be slightly moister and more diverse. The understory of this community type is dominated by bearberry and there is an increase in cover of more mesic plant species like alder, rose, bedstraw and wild lily of the valley. However despite the increase in moisture this community type still occupies very coarse textured sites that are well to rapidly drained.

KUA2 Bearberry/Indian ricegrass (n=2)

(Arctostaphylos uva-ursi/Oryzopsis pungens)

This community type represents open areas on steep south and west facing slopes with coarse textured soils. One site was described on the top of an eroded glaciofluvial kame and graded into an open jack pine/buffaloberry community type. The other site was described in an opening amongst jack pine and bog cranberry and was relatively flat with bedrock at or near the surface. The first site had better developed soils and a higher cover of slender wheatgrass. In contrast the second site had a predominance of lichen and Indian ricegrass (Allen et al. 2002).

KUB1 Juniper/Lichen(Pj) (n=1)

(Juniperus communis/Cladonia spp.(Pinus banksiana))

This community type is very similar to the jack pine/lichen community types that were previously described but appears to be early seral. Fire is extensive throughout the Kazan Upland and jack pine dominated stands will burn frequently. In the absence of disturbance these sites will slowly regrow jack pine.

c blueberry(submesic/medium) (n=12)

Natural Subregion: Kazan Upland

Ecosection: KU Kazan Upland

General Description

This ecosite tends to be subxeric to submesic partly due to coarse-textured parent materials. It is intermediate in both moisture and nutrient regime between the bearberry ecosite (b) and the buffaloberry/alder ecosite (e) as there is some moisture at depth. As such it has species characteristic of the bearberry ecosite such as jack pine, blueberry, bearberry, bog cranberry, Labrador tea, and reindeer lichen and also species characteristic of the buffaloberry ecosite such as aspen, buffaloberry, bunchberry, alder, and fireweed.

Successional Relationships

The pine, aspen, and white birch-dominated phases of this ecosite may, in some cases, succeed to white spruce, however the process is expected to be relatively slow due to the dry nature of these sites.

KUD3 Pj-Aw(Bw)/Bearberry-Bog cranberry (n=4)

(Pinus banksiana-Populus tremuloides(Betula papyrifera)/Arctostaphylos uva-ursi-Vaccinium vitis-idaea)

Community types KUE3 and KUD3 are variants occurring modal conditions for this ecological site differing mainly in their initial secondary successional pathways. This community is very similar to the jack pine/blueberry community type but appears to be slightly moister. The understory of this community type is dominated by blueberry and bearberry and there is an increase in cover of more mesic plant species like alder, rose, bedstraw and wild sarsaparilla. However despite the increase in moisture this community type still occupies very dry coarse textured sites that are rapidly drained at the soil surface.

KUC1 Aw/Rose/Spreading dogbane (n=1)

(Populus tremuloides/Rosa acicularis/Androsace androsaefolium)

In La Butte Creek Wildland Provincial Park, Allen et al. (2002) described this community type on gently sloping fluvial, sandy terraces. This community type also appears to be transitional to the Peace-Athabasca Delta subregion and is associated with the large river systems described in these two subregions. This community type has species characteristic of mesic sites rose, bunchberry and peavine, but it also has species characteristic of drier sites bearberry, spreading dogbane and hairy wildrye. It is intermediate in moisture and nutrients between the blueberry and the buffaloberry dominated ecological sites.

(Carex siccata-Agropyron trachycaulum)

This community type is found on coarse textured, sandy soils. with southerly facing slope. It is generally found on hilltops and steep (>20%) south-facing slopes throughout the Colin Cornwall Lakes Wildland Provincial Park (Allen et al. 2004). This community type generally has better soil conditions than bearberry dominated communities previously described in the bearberry ecological site. This community type was also described on benches and south facing slopes in the Athabasca Plain subregion.

d Labrador tea-mesic(mesic/poor) (n=10)

Natural Subregion: Kazan Upland

Ecosection: KU Kazan Upland

General Description

This ecosite generally occurs in submesic to subhygruic nutrient-poor substrates. Labrador tea and bog cranberry are indicative of the relatively acidic surface soil conditions. It occurs in upland (midslope, upper slope, and crest) or level topographic positions dominantly on till or fluvial over till parent materials. There is commonly a two-tiered even-aged canopy with faster growing jack pine in the higher layer and slower growing black spruce as a secondary canopy. While the Labrador tea-mesic ecosite has plant community types similar to the Labrador tea-hygric ecosite (g), the mesic ecosite tends to occur in upper topographic positions and the presence of mottles in the upper 50 cm. is less common (Beckingham and Archibald 1996).

Successional Relationships

Successionally mature stands that develop on these ecosites may be dominated by black spruce. Residual pine occuring in the climax community are generally very old. The successionally mature stage is rare due to high fire frequency.

KUC4 Aw-Pj-Sb/Labrador tea (n=1)

(Populus tremuloides-Picea mariana-Pinus banksiana/Ledum groenlandicum)

This community type is a moisture variant of the ecological with a slightly richer nutrient regime which favours the growth of aspen and more medium nutrient species like wild sarsaparilla. Successionally mature sites are often dominated by black spruce within this ecological site. The presence of a high cover of aspen and alder indicate the slightly better nutrients. This community type is rapidly drained and has a sandy soil texture at the surface. In the absence of disturbance this community type will likely succeed to a black spruce dominated community.

e buffaloberry/alder(mesic/medium) (n=16)

Natural Subregion: Kazan Upland

Ecosection: KU Kazan Upland

General Description

This is the reference ecosite for the Kazan Upland subregion because it has a mesic moisture regime and a medium nutrient regime. However, the conventional reference site concept of deep, medium textured, well drained and associated vegetation does not generally fit for most of this subregion. The majority of the characteristic sites in this subregion are rocky exposures or dry, rapidly drained coarse glacial deposits. Generally, this ecosite has fine to medium textured glaciolacustrine and glacialfluvial parent materials. This ecological site is located at a mid to lower slope positions where some moisture accumulates. These sites are often dominated by aspen, green alder and buffaloberry and have a high diversity of shrubs and forbs in the understory.

Successional Relationships

Pioneer jack pine and deciduous tree species such as aspen, balsam poplar, and white birch are replaced by white spruce, black spruce and balsam fir as the sites develop successionally. Along with a change in canopy composition is a change in understory structure and understory species composition and abundance. Generally, as a stand successionally matures, the coniferous canopy cover increases, and understory species structure and diversity declines. This results in stands with low cover of shrub, forb, and grass species and high moss cover.

KUC2 Aw(Bw)/Alder (n=3)

(Populus tremuloides (Betula papyrifera))/Alnus crispa)

This reference plant community represents the deciduous phase of the buffaloberry-alder ecological site in the Kazan upland subregion. Moisture and nutrients are intermediate between the drier blueberry ecosite and the moister fern/horsetail ecological site. Succession in the absence of disturbance is to a white spruce climax community.

KUC3 Aw/Buffaloberry (n=4)

(Populus tremuloides/ Shepherdia canadensis)

This community type was found on mesic sites, with shallow slopes and had medium nutrient regimes. Beckingham (1993) felt the Aw/Buffaloberry type was slightly drier and had a slightly poorer nutrient regime than the more modal Aw/Alder or Aw/Low bush cranberry dominated community types. A similar buffaloberry dominated community was described at upper elevations in the Birch and Saddle Hills of the Boreal Mixedwood Natural Region (Moisey et al. 2012).

KUC7 Aw-Pb/Saskatoon-Red Osier Dogwood/Spreading dogbane (n=1)

(Populus tremuloides-Populus balsamifera/ Amelanchier alnifolia-Cornus stolonifera/Apocynum androsaefolium)

This community type was found on mesic to subhygric sites, with shallow slopes and had medium nutrient regimes. The presence of Balsam poplar and red osier dogwood indicate the transition to the moisture and richer ecological site. A similar spreading dogbane community was described in the La Butte Creek Wildland Park but the other site was described on slightly drier sites. Spreading dogbane dominated community types appears to be a provincially rare plant community type and should be recoqnized as a special feature of provincial significance (Allen et al. 2002).

KUD4 Aw- Pj/Alder (n=2)

(Populus tremuloides-Pinus banksiana/Alnus crispa)

A better water supply in the rooting zone due to aspect, finer soil textures at depth or local groundwater flow contributes to better understory growth of alder and feather mosses. Typically these sites are often dominated by a mixture of aspen and jackpine.

KUE6 Sb-Sw/Moss (n=2)

(Picea mariana-Picea glauca/Moss)

This community type represents the climax community type for the buffaloberry-alder ecological site in the Kazan Upland subregion. Pine, aspen and white birch dominated phases of this ecological site are seral to the white spruce dominated climax community. Black spruce once established may occupy a significant portion of the canopy in the climax community (Beckingham and Archibald 1996). On wetter sites in the absence of disturbance white and black spruce dominated communities are also found, but the understory species usually are dominated by a presence of horsetail species.

f red osier dogwood/horsetail (subhygric/rich) (n=2)

Natural Subregion: Kazan Upland

Ecosection: KU Kazan Upland

General Description

The red osier dogwood/horsetail ecosite is subhygric and nutrient rich. These sites are commonly found on level or depressional areas near the base of slopes or near watercourses where they receive nutrient-rich seepage or flood waters for a portion of the growing season. Upland tree dominated ecological sites in the Peace-Athabasca Delta subregion are often this ecological site. Fine-textured till and lacustrine parent materials are common. Horsetails commonly form a blanket over the forest floor.

Environmental Variables

Moisture Regime: Subhygric (moderately moist) (2)

Nutrient Regime: Permesotrophic (rich) (2)

Elevation (range): 217.5 (200-235) M

Slope (%): level (1), nearly level (1)

Aspect: Level (1), Westerly (1)

Topographic Position:Level (1), Upper Slope (1)

Soil Variables

Soil Drainage: Imperfectly drained (1), Moderately well drained (1)

Soil Subgroup: LUVIC GLEYSOL (1)

Surface Texture: Silty clay (1)

Effective Texture: Silt loam (1)

Depth to Mottles/Gley: 26 - 50 (1)

Organic Thickness: 0 - 5 cm (1)

Parent Material: Lacustrine (1)

Humus Form

LFH Thickness	Mean	Min	Max	Count
cm:	5.00	5.00	5.00	1

Successional Relationships

Succession on these rich sites proceeds slowly after disturbance due to the proliferation of grass, forb and shrub cover. This explosion of vegetational cover can make tree establishment (especially coniferous) difficult and can reduce early growth rates. Once white spruce becomes established, high growth rates can be expected.

KUC5 Pb/Alder-Red osier dogwood/Horsetail (n=1)

(Populus balsamifera/Alnus tenuifolia-Cornus stolonifera/Equisetum pratense)

This plant community is transitional to the Peace-Athabasca subregion and is found in lower slope topographic positions near water courses where it receives nutrient-rich seepage or flood waters for a portion of the growing season. Undisturbed, this plant community tends to have dense shrub cover. Light is limited for lower herbaceous layers and succession in the absence of disturbance will be to white spruce.

g Labrador tea-hygric(hygric/medium) (n=2)

Natural Subregion: Kazan Upland

Ecosection: KU Kazan Upland

General Description

The Labrador tea-hygric ecosite has a nutrient poor substrate with imperfectly to very poorly drained soils. Labrador tea and bog cranberry are indicative of the relatively acidic surface soil conditions. The Labrador tea - hygric ecosite has plant community types similar to the Labrador tea - mesic ecosite the hygric ecosite tends to be in mid to lower slope positions, has distinct mottling within the top 50cm of soil and tends to be dominated by black spruce rather than pine.

Successional Relationships

Young and mature stands developing in this ecosite often have a component of black spruce. The black spruce is often the same age as the pine but forms a secondary canopy due to slower growth rates. Successionally mature stands are dominated by black spruce with a small component of old residual pine.

KUE10 Lt-Sb/River alder/Sedge (n=1)

(Larix laricina-Picea mariana/Alnus tenuifolia/Carex spp)

Fen ecosites are not common in the Canadian Shield natural region. Most wetlands are situated in the bog or poor fen ecosites because of the acidic nature of the soils in the region. Micro-topography allows trees to grow on slightly higher ground and contributes to species richness. Increased flooding and prolonged water-logging may result in the disappearance of trees and a transition to a willow/sedge fen.

h bog (subhydric/very poor) (n=3)

Natural Subregion: Kazan Upland

Ecosection: KU Kazan Upland

General Description

Bog communities are the dominant wetland type in the Kazan Upland subregion. The bog ecosite has a very poor to poor nutrient regime and is poor to very poorly drained. Organic soils consisting of slowly decomposing peat moss are common. This ecosite occupies level and depressional areas where water tends to be stagnant and impeded drainage or high water tables enhance the accumulation of organic matter. Stunted black spruce forms a sparse canopy on the treed phase (h1) of the bog ecosite. Leatherleaf (Chamaedaphne calyculata) is very common in the bog ecosite.

Environmental Variables

Moisture Regime: Subhydric (moderately wet) (3)

Nutrient Regime: Oligotrophic (very poor) (1), Submesotrophic (poor) (2)

Elevation (range): 267.5 (230-300) M

Slope (%): level (1), very gentle slope (1)

Aspect: Level (1), Northerly (1)

Topographic Position:Lower Slope (1), Depression (2)

Soil Variables

Soil Drainage: Poorly drained (1), Very poorly drained (2)

Soil Subgroup: FIBRISOL (1), GLEYSOL (1), ORGANIC CRYOSOL (1)

Surface Texture: Fibric (2)

Effective Texture: Mesic (1), Sand (1)

Depth to Mottles/Gley:

Organic Thickness: 26 - 39 cm (1), 60 - 79 cm (1)

Parent Material: Glaciofluvial (1), Undifferentiated Organic (2)

Humus Form

Successional Relationships

The bog ecosite is an edaphic climax that is maintained by water tables. The hydrarch succession that leads to the bog ecosite is extremely slow.

KUB2 Labrador tea/Peat moss (Sb) (n=2)

(Ledum groelandicum/Sphagnum spp (Picea mariana))

This plant community represents an early seral community of the treed bog ecosite phase. The bog ecosite commonly has organic soils consisting of slowly decomposing peat moss. In the absence of disturbance this community type will become dominated by black spruce. The soils for one plot in this community type was described as peaty phase of a Rego Gleysol as the soil was described at the outer edge of the bog.

Ecosite: h bog (subhydric/very poor)

General Description

This ecological site phase currently has no data and graminoid bogs have not been described in the Boreal Natural Region. This ecological site phase was created for photo interpretation of vegetation for Alberta Vegetation Inventory (AVI) and Primary Land Vegetation Inventory (PLVI) if the interpreters call for a mapcode of 9B (Hydric/very poor). If interpreted in the various vegetation land cover inventories it will provide a spatial location in which to sample.

i poor fen (subhydric/medium) (n=3)

Natural Subregion: Kazan Upland

Ecosection: KU Kazan Upland

General Description

The poor fen ecosite is intermediate in nutrient regime between the bog (h) and the rich fen (j) ecosites and as such has species characteristic of both. Drainage is poor to very poor, however, there is some movement of water through the substratum. This ecosite occupies level and depressional areas where impeded drainage or high water tables enhance the accumulation of organic matter. This organic matter consists of a combination of bog-type organic matter (peat moss) and rich fen-type organic matter (sedges, golden moss, tufted moss, and brown moss). Both the black spruce and/or tamarack that dominate a sparse canopy on the treed phase (i1) of the poor fen ecosite are stunted and generally considered unmerchantable. A number of saline influenced plant community types were described here (KUA4, KUA5). In the Northern Mixedwood subregion a saline lowland ecological site was described, but the saline ecological sites in the Kazan Upland are presently not adequately described that warrants a new ecological site.

Successional Relationships

Succession within this ecosite occurs over periods of hundreds to thousands of years. Recovery from disturbance is extremely slow. Changing hydrologic regimes that can result from disturbance influence the direction and rate of succession. These systems depend on water flow through them, impeding this flow can result in reduction or elimination of tree cover and changes in the shrub, forb and grass layers (Beckingham and Archibald 1996).

KUA4 Shooting star/Mat muhly (saline) (n=1)

(Dodecatheon pulchellum/Muhlenbergia richardsonis)

This community type is part of a saline meadow complex described within the La Butte Creek Wildland Provincial Park (Allen et al. 2002). Site 1 which is described was slightly drier and was dominated by mat muhly, shooting star and seaside arrow grass. The other site which was slightly wetter was dominated by brown moss, awned sedge and seaside arrowgrass on the drier margins. It was felt that the mat muhly dominated community was subjected to higher levels of salt through evaporation.

Humus Form

j rich fen (subhydric/rich) (n=3)

Natural Subregion: Kazan Upland

Ecosection: KU Kazan Upland

General Description

The rich fen ecosite is characterized by flowing water and alkaline nutrient-rich conditions. The soil is composed of organic matter derived from decomposing sedges, as well as golden, tufted, and brown mosses. This ecosite occupies level and depressional areas where the water table is at or near the surface for a portion of the growing season. Tamarack dominates the canopy on the treed phase while dwarf birch or willow form the canopy of the shrubby phase, and sedges dominate the graminoid phase of the rich fen ecosite. A number of sites within this ecological site were described with mineral soils. According to the Alberta Wetland Classification system (2015) mineral soils can only be swamps or marshes, however because of the species composition and moisture regime these willow and sedge dominated communities for this classification were placed within the rich fen ecological site.

Environmental Variables

Moisture Regime: Hydric (wet) (1), Subhydric (moderately wet) (1), Subhygric (moderately moist) (1)

Humus Form

Successional Relationships

The rich fen is an early stage in hydrarch succession. Species composition, and direction and rate of succession changes with the changing hydrologic regime. As with other wetlands, rich fens have slow successional rates, so recovery from disturbance may also be slow.

KUB3 Willow/Marsh reed grass (n=1)

(Salix spp/Calamagrostis canadensis)

This plant community is found along the edges of marsh reed grass and sedge fen meadows and in moist depressions. Willow will invade onto these graminoid fens to form the Willow/Marsh reed grass community type. Increased flooding and prolonged waterlogging may result in the disappearance of willow and a transition to a graminoid fen.

Effective Texture: Silt (1)

Depth to Mottles/Gley:

Organic Thickness: 0 - 5 cm (1)

Parent Material: Fluvial (1)

Humus Form

KUB4 Willow/Sedge (n=1)

(Salix planifolia/Carex utriculata)

This community type is found along the edges of sedge fens (meadows) and in moist depressions. Willow becomes established at the edges of the sedge fens due to the shorter duration of standing water. Increased flooding and prolonged water-logging may result in the disappearance of willow and a transition to a sedge fen.

Natural Subregion: Kazan Upland
Ecosection: KU Kazan Upland

Ecosite: j rich fen (subhydric/rich)
Ecosite Phase: j2 rich fen - shrubby

Plant Composition

Canopy Cover (%)

	Mean	Range	Const.
Tall Shrub (2 to 5m)

Parent Material: Fluvial (1)

Humus Form

KUC8 Willow/Brown moss/ Aw(Bw) (n=1)

(Salix pyrifolia/Drepananocladus aduncus)

This community type is found along the edges of sedge fens (meadows) and in moist depressions. Willow becomes established at the edges of the sedge fens due to the shorter duration of standing water. Increased flooding and prolonged water-logging may result in the disappearance of willow and a transition to a sedge fen. If the water table continues to decline the site will eventually become dominated by Aspen and birch.

k marsh (hydric/rich) (n=3)

Natural Subregion: Kazan Upland

Ecosection: KU Kazan Upland

General Description

Marshes can be locally extensive in sheltered lake bays or along creek channels and are dominated by water and small bottle sedge, bulrushes and in deeper water pondweeds (Natural Regions Committee 2006). All the information for this ecological site is copied from the Central Mixedwood (marsh (l)) (Beckingham and Archibald 1996).

The marsh ecosite is found in level and depressional areas and around the shorelines of water bodies and riparian zones. The water is above the rooting zone for at least a portion of the growing season. These ecosites are dominated by a high diversity of emergent sedges and rushes.

Environmental Variables

Moisture Regime: Hydric (wet) (3)

Nutrient Regime: Eutrophic (very rich) (3)

Elevation (range): 231.33 (200-284) M

Effective Texture: Undifferentiated Organic (0)

Depth to Mottles/Gley:

Organic Thickness:

Parent Material: Water (0)

Humus Form

Successional Relationships

The marsh ecosite is near the beginning stages of hydrarch succession. The marsh ecosite can be thought of as successionally stable, but overtime will evolve into bogs and fens through the processes of terrestrialization (filling of shallow lakes) and palludification (blanketing of terrestrial ecosystems by overgrowth of wetland vegetation) (http://www.aquatic.uoguelph.ca/wetlands/chapter2/bogpage2.htm) both processes caused by accumulating organic matter.

Indicator Species

Forb

NORTHERN QUILLWORT
Isoetes echinospora

WATER ARUM
Calla palustris

WATER PARSNIP
Sium suave

Graminoid

NORTHERN MANNA GRASS
Glyceria borealis

k1 marsh (n=3)

Natural Subregion: Kazan Upland
Ecosection: KU Kazan Upland

Ecosite: k marsh (hydric/rich)

Characteristic Species

Forb

[31.6] WATER ARUM*
Calla palustris

Organic Thickness:

Parent Material: Water (0)

Humus Form

KUA6 Water parsnip/Northern manna grass (n=1)

(Sium suave/Glyceria borealis)

This community was described in 2 m wide widths along stretches of the La Butte Creek in the La Butte Wildland Provincial Park (Allen et al. 2002). This community represents a floating-leaved aquatic community. The center of the creek was occupied by submerged vegetation usually dominated by clasping-leaf pondweed. Moving towards shore this community occupied the next zone of vegetation, followed by a band of emergent creeping spike-rush along the shoreline.

Natural Subregion: Kazan Upland
Ecosection: KU Kazan Upland

Ecosite: k marsh (hydric/rich)
Ecosite Phase: k1 marsh

Humus Form

KUA7 Northern quillwort (n=1)

(Isoetes echinospora)

This community type was described along La Butte (Allen et al. 2003). This community was found in a band close to the shoreline on a sandy substrate in water 0-30 cm deep. It was also noted that the consistency of the water depth for this community type was striking and suggests that this community type inhabits sands in shallow water around the entire lake. Other aquatic species noted in this community type include water milfoil and pondweeds.

Natural Subregion: Kazan Upland

KUA8 Water arum/Sedge (n=1)

(Calla palustris/Carex pseudocyperus)

This community type was described around the open pools of water in an old meander channel along La Butte Creek near the Slave River in La Butte Creek Wildland Provincial Park (Allen et al. 2002). This community type was best expressed where the water table was about 1m deep. It was noted that open water covered about 50% of the plot.
