### Abstract

The present paper elaborates the results of vegetation and floristic research carried out in the valley of Hunza, Central Karakorum Mountains, northern Pakistan. The field surveys conducted from 2011 – 2012 ended with the collection of 324 species in 183 genera and 48 families. Based on geo-climatic conditions and floristic assemblage the vegetation of the studied area can be categorized into three altitudinal belts i.e. temperate, sub-alpine, and alpine. Altitude exhibits profound impacts on the species richness, composition, and surrogacy. The species diversity declined with elevation and maximum species richness was observed at the temperate belt. Asteraceae was the most presented family with 83 species followed by Poaceae (29 spp.), Fabaceae (16 spp.), and Cyperaceous (16 spp.). Perennial herbs (77%) were the leading habit with sub-dominating shrubs (11%) and annuals (9%). In life-form categories, hemicryptophytes presented 249 species followed by therophytes and nanophanerophytes with 29 species each. Similarly, the common habitat of dry mountain slopes support maximum species i.e. 106 species followed by ruderal (90 spp.), and moist mountain slopes (84 spp.). The assessment for quantitative thresholds for conservation revealed that habitats of 28 taxa were observed unstable, 255 taxa exhibited habitat specificity, 75 showed small population size, and 65 presented small geographical range. The application of IUCN Red List Criteria 2001 (Version 3.1) disclosed that 38 species fell in critically endangered, 32 vulnerable, and 10 endangered categories. The current ecological and floristic appraisal of the studied area would be effective to devise and strengthen the conservation strategies of climatically fragile mountain ecosystems.

**Key words:** Phytodiversity, Vegetation zones, Ecology, Mountain ecosystem.

### Introduction

Biodiversity is the most astounding and complex feature of our planet. Being the abundant producers, plants have vigorous role to drive ecological processes which uphold ecosystem and support life (Loreau, 2000; Pavlov and Bukvareva, 2007). An estimated total of 500,000 species of plant contribute in the global biological diversity (Corlett, 2016). Human activities have greatly altered global environments, declined biological diversity, caused extinctions and reduced the population sizes of surviving species (Yule *et al.*, 2013). The impacts of these actions are more damaging in the mountain ecosystems because of their fragile nature, rapidly changing global climate, severe environmental hazards and unsustainable resource utilization by underprivileged human societies (Beniston, 2002, 2016).

This jeopardizes all biological entities of mountain ecosystems particularly plants due to their sessile nature. It is estimated that extinction risk for 96% of all described plant species is yet to be evaluated worldwide(Brooks *et al.*, 2002; Sheth *et al.*, 2008). Therefore, a preliminary conservation assessment of the conservation status of all known plant species at national, regional and international levels was one of the prime objectives of the Global Strategy for Plant Conservation by 2010. Developed countries have been paying particular attention to identify

and protect threatened plants for two decades. They have established comprehensive criteria to detect species extinction risk (Nature *et al.*, 2001). Unfortunately, this knowledge is very limited in developing countries (Alam, 2010; Alam & Ali, 2010).

Pakistan presents remarkable phytodiversity with more than 6000 species (Ali, 1986, 2008).They experience tremendous pressure due to burgeoning human population, rampant urbanization, agricultural encroachment and unsustainable resource utilization particularly the montane flora (ABBAS *et al.*, 1998; Khan, 2007). On the other hand, we could not be able to develop red list of all threatened plants yet. In the recent decades, very little critical field work has been done on “threatened plants” of the country according to IUCN red list criteria 2001(Nature *et al.*, 2001). To date, only 142 flowering taxa have been evaluated based on this criteria (Abbas *et al.*, 2010; Ali & Qaiser, 2010; Ali *et al.*, 2012; Majid *et al.*, 2015; Muhammad *et al.*, 2017). This figure hardly makes c. 2% of total known flowering plant species of Pakistan. Thus, it is obvious that limited information of threatened plants we have been failed to adopt restorative measures for hundreds of plants likely to be extinct in due course of time.

Therefore, the current study has been conducted in the valley of Hunza with the objectives 1) to explore the floral diversity 2) to assess the ecological features 3) to evaluate the collected plants species according to IUCN criteria 2001.

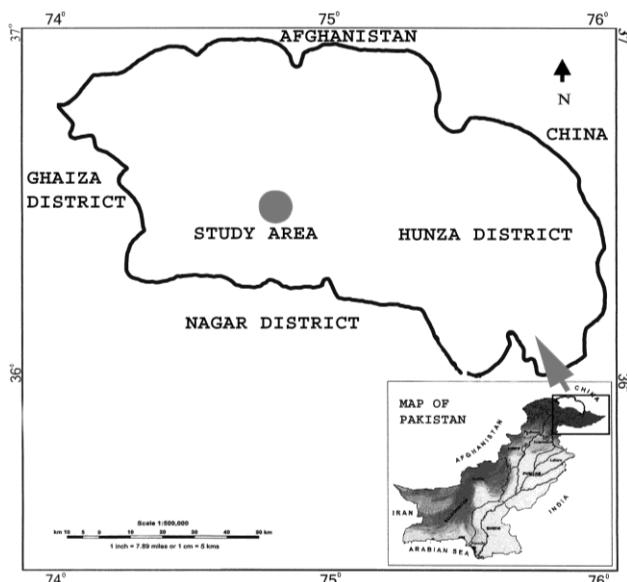

Fig. 1. Map of the study area.

## Materials and Methods

**Study area:** Hunza valley ( $36.3167^{\circ}$  N,  $74.6500^{\circ}$  E) is located at the elevation of 2000m in the western part of Central Karakorum Ranges, Gilgit-Baltistan, Pakistan (Fig. 1). Administratively, it is a newly formed district and borders with the People Republic of China in the east, Ghizir in the west, Chitral in the north and Baltistan and Nagar in the south. Topographically, the valley is rugged and dry with some high peaks above 7000m and permanent glaciers are also located like Ultar Peak-I & II, Ultar glacier & Shishpar glacier. It experiences mild summer and cool winter while the mountaintops possess arctic climate (Sidky, 1995). Below 3000m, precipitation rarely exceeds 200 millimetres annually. However, there is a strong gradient with altitude and at 6000m, the snow fall is equivalent to 2000 millimetres per year. Temperature in valley bottoms can range from extremes of nearly  $40^{\circ}\text{C}$  in the summer to less than  $-10^{\circ}\text{C}$  in winter (Owen *et al.*, 2002). The Hunza River flows north to south, and is joined by several other rivers i.e. Shimshal, Batura, Passu, Ghulkin, Misgar, Chapurson, Gojal and Gulmit. The total population of Central Hunza is 20,000, of which 5,700 people live within the bottom villages of the Central Hunza Mountains—Karimabad, Haiderabad, Aliabad Hassanabad and Murtazaabad. Mostly of the human population is settled at the base of the valley (Alam & Ali, 2010; Ali, 2000). By and large, these villages are located on fluvial terraces and debris fans. Generally, growing period of the flora is from March to end of September. In the valley bottom, plant

growth starts usually from March, while in alpine and sub-alpine zone the growing season starts from May (Alam, 2010). On the irrigated fields, wheat and potatoes are the dominant crops grown. Apricot, apple and cherry trees are extensively cultivated in orchards and are intercropped with vegetables such as peas, onions, tomatoes, carrots, cabbage and other greens. Sea-buckthorn (*Hippophae rhamnoides*) and poplar trees (*Populus spp.*) are important for fodder and fuel. These woody species, interspersed with grass, growing near the glacier termini, on slopes steeper than  $12^{\circ}$ , adjacent to glacial streams or lining the irrigation channels, and are used to stabilize such locations (Eberhardt *et al.*, 2007). Ecologically this area shows a high floristic diversity in response to diverse climatic and edaphic conditions. Flora resembles with the central Asiatic elements and included in Irano-Turanian phytogeographical region (Ali & Qaiser, 1986; Eberhardt, 2004).

**Data collection:** Field trips were carried out in the study area in two consecutive vegetation peak seasons from 2010-2011. The studied area was delineated in different altitudinal ecological zones based on altitude, topography and environmental conditions as described by (Abbas *et al.*, 2019b) and Dickoré & Nüsser (2000). The geographical information (Latitude, Longitude and Altitude) was recorded at each collecting sites with the help of Geographical Positioning System (GPS). Habitats were examined carefully and noted the sign of environmental hazards for instance soil erosion, over-grazing, land tilling, fuel wood consumption etc. Plants species were sampled from variety of habitats and endeavored to cover the maximum elevation ranges of the area. The gathered specimens were examined carefully and classified into different growth habit and life form (Raunkiaer, 1934). The distribution and abundance of the taxa was also determined following the criteria proposed by Rabinowitz (1981) Table 1. Finally, all collected plant species were evaluated according to IUCN Red List Categories and Criteria 2001 (Nature *et al.*, 2001). The specimens were pressed, dried and mounted after going through proper herbarium techniques as per international standards (Bridson *et al.*, 1992). The nomenclature based on Flora of Pakistan [Nasir & Ali, 1970-1989 (Nos 1-190); Ali & Y. Nasir, 1989-1991(Nos. 191-193); Ali & Qaiser 1993-2021 (Nos. 194-225)], Annotated Catalogue of the Vascular Plant of West Pakistan and Kashmir (Stewart *et al.*, 1972) and flora of China ([www.efloras.org](http://www.efloras.org) → flora\_page → flora\_id=2.) The specimens of concerned taxa cited in the Flora of Pakistan housed in Hazara University Herbarium (HU) and Karachi University Herbarium (KUH) were also consulted. Finally, voucher specimens were deposited at Hazara University Herbarium.

Table 1. Abundance criteria of taxa (Rabinowitz, 1981).

Abundance	Condition
Very common	If a taxon is distributed almost every ecological zone (except Permanent snow line zone) and number of individual more than 500 at each location in the study area or frequently cultivated
Common	If a taxon is distributed within two ecological zones and number of Individuals 51-499 at each location in the study area or moderately cultivated
Rare	If a taxon is distributed within a single location and confined to single habitat or sparsely distributed in few locations in the area or number of individuals are less than 50 individuals

## Results

The results describe the floral attributes (families, genera, species), physiognomy (habit, life form), distribution (ecological zonation, habitat types) and conservation (habitat quality, habitat specificity, population size, geographic range, and IUCN criteria, IUCN category).

### Floral attributes

**Taxonomic diversity:** A total of 324 species belonging to 48 families and 183 genera were recorded from the study area. Among these, 5 (1.5%) species, 2 (1.09%) genera and 2 (1.54%) families were gymnosperms. Similarly, 56 (17.28) species of monocots were distributed in 29 (15.8%) genera and 6 (17.2%) families. The remaining 263 species (81.17%), 152 (83.06%) genera and 39 families were dicots. Asteraceae was the leading family with maximum representation of 83 species (25.6%) among dicot species. Fabaceae, Rosaceae and Caryophyllaceae were sub-dominant families with 16, 14 and 14 species respectively (Fig. 3). The remaining families contributed as, 10 families had 5-13 species, 16 families with 2-4 species and 10 families with 1 species each. Poaceae was the largest monocot family with 29 species followed by Cyperaceae with 16 species. Other 4 families were represented by 1- 6 species. A complete check list and relevant attributes of the plants of the study area is presented in the Table 2. Some representative plants species were depicted in Fig. 4.

**Habit and life form:** Habit-wise, perennial herbs prevailed with 250 species (77.1%), followed by shrubs with 37 species (11.41%), annual herbs having 29 species (8.95%) and arboreal habit 3(0.009%) tree species. Based on life form variability, Hemicryptophytes were maximum with 249 species (76.8%), Therophytes and nanophanerophytes made the second abundant group with 29 species (8.95%) each. The contribution of Chamaephytes (9 species, 2.77%), megaphanerophytes (4 species, 1.23%) Geophytes (3 species, 0.92%) and 1 parasitic species was recorded (Table 3).

### Altitudinal zonation of vegetation

**Temperate zone (TMP):** Below 3000m, the area can be demarcated as temperate zone. A sum of 142 species has been sampled from this zone. The upper portion of the zone consists on dry rock slopes and stream banks. Even within the irrigated land, the upper portion has been specified for fuel wood, timber, fruit and fodder-related taxa, while the lower portion is used for crop cultivation. Dry sandy slopes are also present among cultivated land. Many cultivated tree species are grown in this vegetation belt like *Populus siberica*, *Eleagnus angustifolia* and Shrubs like *Hippophae rhamnoides* subsp. *turkistanica*, *Daphne mucronata*, and *Colutea paulsenii*. Similarly many herbs like *Cichorium intybus*, *Campanula chashmiriana*, *Lactuca tatarica* grow as weeds among cultivated fields especially grasses.

**Sub-alpine zone (SBA):** This zone usually extends from 3000 to 3700m. Both shrubby and herbaceous species were found to occur in different combination depending upon the aspect of the slopes. One hundred two (102) taxa were recorded from this vegetational belt. Many micro habitats were seen in this zone and this was mainly due to slope aspects of the mountains. Shrubs were represented by *Ribes alpestre*, *Rosa webbiana*, *Lonocera heterophylla*,

*Sorbus tianschanica*, *Spiraea hypericifolia*, *Juniperus excelsa*, *Juniperus turkistanica*, *Potentilla salesviana* etc. while herbaceous species like *Hedysarum falconeri*, *Cicer microphyllum*, *Astragalus peduncularis*, *Pseudomenrtensia echoidea*, *Aquilegia fragrans*, *Inula royleana* and *Artemisia brevifolia*, *Rosa webbiana* were recorded.

**Alpine zone (ALP):** This zone may be recognized from 3700m up to permanent snow line limit. Eighty (80) species were documented from this zone. Vegetation consisted of on dwarf shrubs (prostrate of less than 1m tall) and herbs. Twenty four exclusively confined species are recorded for this belt including *Primula macrophylla*, *Anaphalis nepalensis*, *Allardia nivea*, *Allardia tomentosa* and *Anemone rupicola*. The zone exhibits several micro habitat types i.e. scree, boulders, meadows, glacial moraines etc. This provides a good pasture land for the local community (Fig. 2).

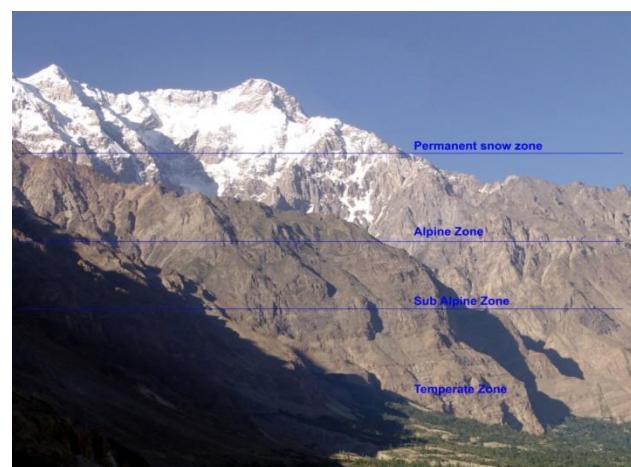

Fig. 2. Depiction of altitudinal zonation of the vegetation.

**Habitat diversity:** Although, the area is a home land for numerous micro habitats, however, the study area has been classified into the following five main habitats: Feld-mark, moist mountain slopes, dry mountain slopes, river-stream bank and cultivated lands.

**Feld mark (FLD):** This habitat can be seen in the upper portion of alpine zone. It is mostly degraded and with a thin layer of soil due heavy snow fall and fast wind blow. Vegetation is highly sparse and few species are documented from this habitat. Eight species were recorded in Feld mark habitat. Highly adaptive species can only be grown there like *Allardia tomentosa*, *Allardia nivea*, *Anaphalis nepalensis* var. *nepalensis*, and *Primula* sp.

**Moist mountain slopes (MMS):** Moist mountain slopes can be seen on the northern and eastern facing slopes in alpine and sub-alpine zones. Vegetation is dense and 84 species were recorded from this habitat. Direct sun intensity is less and as result moisture remains for a long period. Many shrubs like *Salix* sp., *Sorbus tianschanica*, *Clematis sibirica* var. *alpina* and many herbs like *Geranium himalayense*, *Rhodiola tibetica*, *Rhodiola wallichiana*, *Saxifraga flagellaris*, *Inula royleana*, *Viola rupestris*, *Anemone rupicola*, *Aquilegia fragrans*, *Delphinium chasmeriana*, *Codonopsis clemididea*, *Erigeron multicaulis*, *Pseudomenrtensia echoidea*, *Myosotis alpestris* and *Silene kunawarensis*.

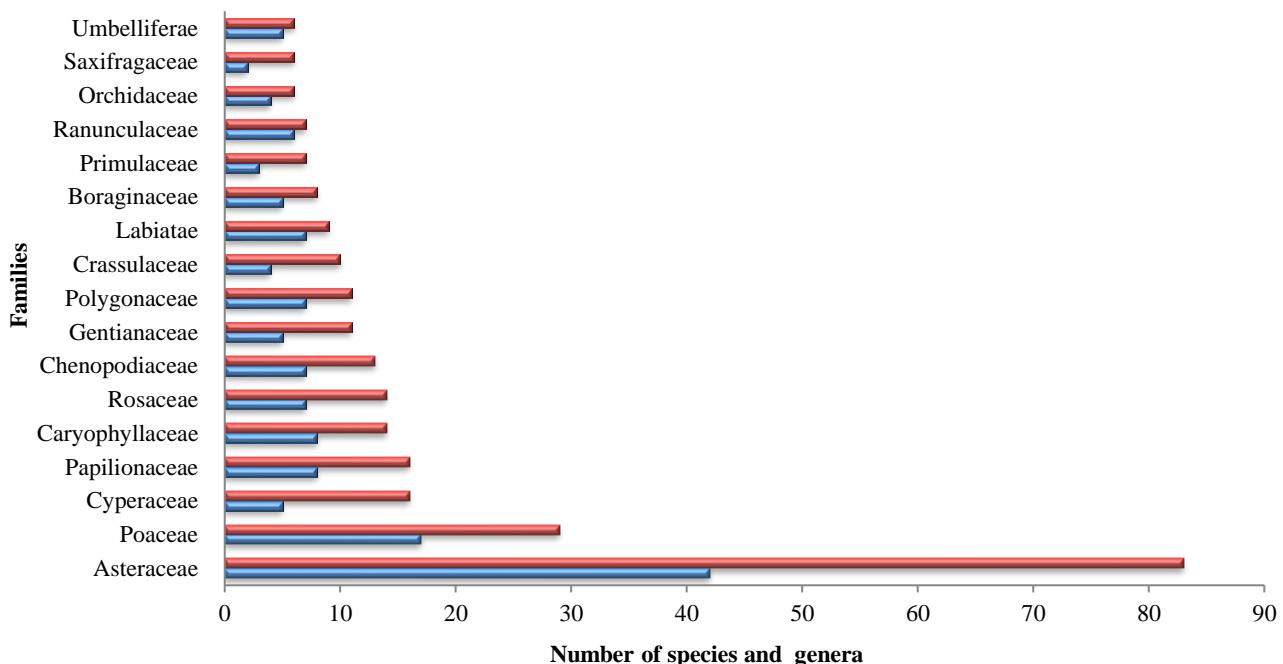

Fig. 3. Distribution of species in the ten dominant families of the study area.

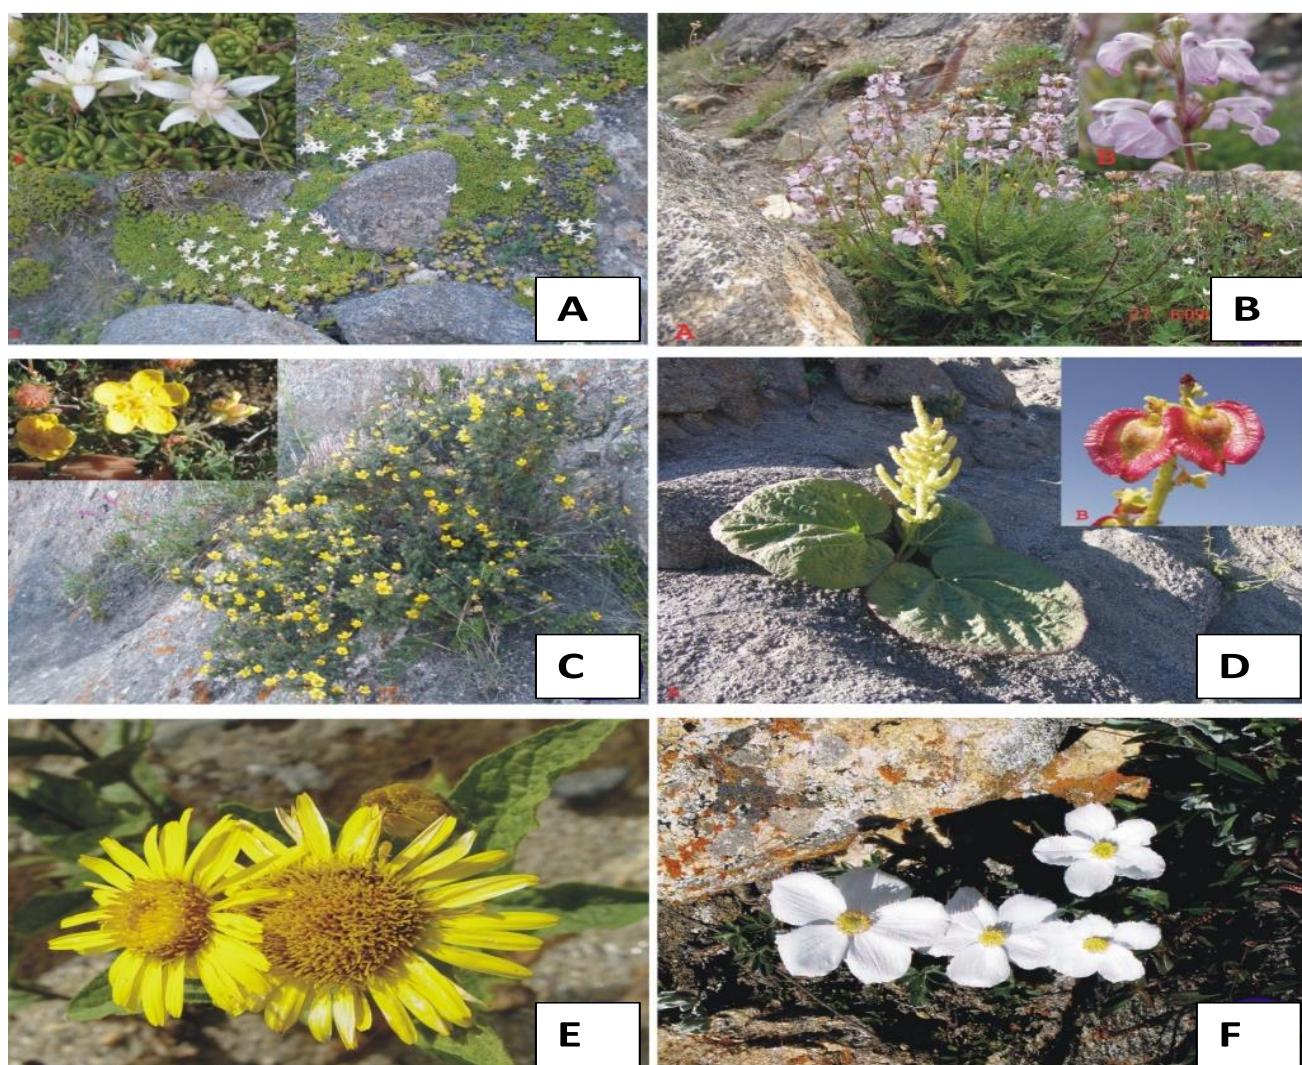

Fig. 4. Some representative species of the study area **A**) *Rhodiola saxifragoides* **B**) *Pedicularis staintonii* **C**) *Potentilla ochreata* **D**) *Rheum tibeticum* **E**) *Inula obtusifolia* **F**) *Anemone rupicola*.

**Dry mountain slopes (DMS):** This habitat can be seen on the southern and western facing mountain slopes in the study area. Direct sunlight remains for a long period in each sunny day. Therefore, these slopes remain dry for most of the year. Maximum species (106) species were recorded from DMS habitat. Many trees and shrubs such as *Juniperus excelsa*, *Juniperus turkistanica*, *Potentilla ochreata*, *Lonicera heterophylla*, *Rosa webbiana*, *Spiraea hypericifolia*, *Ribes alpestre*, *Berberis* sp., *Rhamnus postratus*, *Artemisia brevifolia*, *Acantholimon lycopodioides* alongwith number of herbs like *Hedysarum falconeri*, *Chesneya cuneata*, *Astragalus peduncularis*.

**River-stream banks (RSB):** Stream and river were the major aquatic habitat types and represent unique vegetation including 36 species. Many species were confined to this habitat. *Epilibium angustifolium*, *Peonia emodi* and *Shangwua jacea* were some examples for this habitat. The established riverine forest provides fodder for the mountain agro-pastoral communities.

**Cultivated land (CLD):** Bottom of the valley is used for cultivation. Many species are grown there for timber, fuel wood and other purposes. A total of 90 species recorded from cultivated lands as ruderal species. Among these species, many wild species are *Campanula pallida*, *Astragalus falconeri*, *Tribulus terrestris*, *Peganum harmala*, *Swertia cordata*.

### Conservation

**Abundance, habitat quality and specificity:** The assessment for the collected species reported that 130(40%) species were rare, 190(55%) common and only 4(1.2%) species were very common. It was noted that the species 296 species was found on stable habitats while only 11 species had disturb and unstable habitat types. The analysis of habitat preference by the documented

**Table 4. Abundance and IUCN criteria and categories of taxa.**

	Rare	130
Abundance	Common	190
	Very common	4

	A, B	3
IUCN Category	Critically endangered	38
	Vulnerable	32
	Endangered	10

species revealed that 253 species showed habitat specificity while the remaining 71 species did not show any specificity with their habitats.

**Small population size and geographic range:** The evaluation of population size of the collected species revealed that 75 five species were with small population. However, the proportion of those species having large and established population was in number. Similarly, 259 species showed wide geographic range while 65 plants were showed small geographic range.

**IUCN red list categories and criteria, and endemism:** IUCN red list categories criteria 2001 (IUCN, 2001) was consulted in order to evaluate the conservation status of the taxa. Geographic range (B), Population size (A= reduction in population size; C = small population size; D = extremely small population size) and other associated data was used for this purpose (i.e. habitat specificity, quality of habitat and exploitation of the species for various purpose etc.). It showed that maximum species (53 spp.) were fallen in BC category. Ten (10) species in B category; 3 species in A,B; 6 in A,B, C; 1 species in A, B, D; 1 in C and the remaining 1 species in D category. Finally, based on the above facts, 38 species assigned as critically endangered (CR), 10 species endangered (EN) and 32 species assigned under vulnerable (VU) Table 4. In the view of conservation, it is necessary to identify threatened species. Endemic and rare species are very important in this connection. Both categories have been discussed separately as, Six endemic species were collected from the area i.e. *Aconitum violaceum* var. *weileri*, *Rhodiola saxifragoides*, *Tanacetum baltistanicum*, *Asperula oppositifolia* subsp. *baltistanica*, *Hedysarum falconeri*, and *Pedicularis staintonii*. Among above mentioned species, *Asperula oppositifolia* subsp. *baltistanica* is exclusively endemic to the area, while the remaining species are also found some other areas of Pakistan. Even within their entire distribution area, these

taxa are rare and also in the study area due to habitat specificity, small population size or limited distribution. It should be noted that, in the above species, *Asperula oppositifolia* subsp. *baltistanica* and *Tanacetum baltanicum* have already been declared as Critically Endangered; and *Rhodiola saxifragoides* and *Aconitum violaceum* var. *weihlerei* as vulnerable for Pakistan due to limited distribution area, habitat degradation and small population sizes (Alam, 2010). Therefore, special attention should be paid in the area in order to ensure their survival.

## Discussion

Study area harbors substantial floristic diversity and presents ferns and seed plants. Angiosperms were the most successful group due to their adaptations with varied habitat types. These outcomes congruence with the previous studies conducted in the range of Karakorum for instance of Abbas *et al.*, (2019b), Abbas *et al.*, (2019a), and (Abbas *et al.*, 2017). Asteraceae is one of the largest families of Pakistan flora published with 21 tribes. Family Asteraceae is known as highly advanced family with specialized morphology and ecological niche. It assorts in all world biomes from tropics to Polar Regions and represents 10% of the total angiosperm flora (Barreda *et al.*, 2012; Bremer and Anderberg, 1994). Being mountainous terrain the climatic conditions and ecological profile embolden the growth of herbaceous plants. The lower tree line comprises of cultivated tree species mostly belong to family Rosaceae e.g. *Prunus armeniaca*, *Pumila malus*, *Prunus amygdalus*, *Prunus persica*, *Prunus avium* etc. The upper tree line determines by *Betula utilis* similar to other Karakorum valleys (Abbas *et al.*, 2020). The biological diversity of plants of any region depends upon landscape and habitat diversity (Amoros, 2001; Brooks *et al.*, 2002). Although the surveyed area exhibits semi-arid region due to scanty rain fall. However, moisture, topography and climatic conditions change with respect to elevation supporting diverse habitat types. The main habitat type is the dry mountain slopes and reside maximum plants species. Nowak *et al.*, (2014) and Akhani *et al.*, (2013) reported same findings from the semi-arid region of Pamir Tajikistan and Iran respectively. Hemicryptophytes are considered to be the best adapted plant group for harsh and cold mountainous environment due to its hidden perennating buds in unfavorable conditions (Klimes, 2003; Pavón *et al.*, 2000). Maximum species were sampled from Temperate Zone. Lower temperate zone enjoys comparatively abundant moisture due to agricultural activities. Since, the waste lands also support a number of ruderal species. Being the semi- arid terrain dry mountain slopes were the most prevailed habitat type. The most of the collected species showed common distribution with stable habitat. It indicates the large extent environmental stability for the growing taxa. On the other hand, considerable taxa grow at specific habitat. This habitat specificity makes the taxa susceptible for environmental degradations and may jeopardize their survival (Alam & Ali, 2010). Small geographic range (65) and population size (75) also make the taxa more vulnerable. The assessment through IUCN red list criteria,

38 were critically endangered followed by 38, vulnerable 32 and endangered 10. During the study few endemic species and most of the species showed specific habit, low population size and small geographical range. The endemic species are consider being more susceptible of environmental fluctuations and threats due to their narrow niche and restricted distribution (Abbas *et al.*, 2013). Therefore, the study advocates the vulnerability and risk to these species inviting special attention to ensure the protection for their survival. Effective conservation action plans are needed at priority bases to protect them from local elimination and extinction.

## Acknowledgement

Higher Education Commission (HEC) Islamabad, Pakistan is highly obliged for funding the research project.
