Abstract

A critical revision of the Monocotyledoneae comes to the recognition of 282 species of 17 families being properly known from or likely to occur in the Karakorum mountains. Four new species are described and seven new combinations are made. Distributional and ecological data are annotated for the taxa occuring in the Karakorum, keys are included where possible. The flora of the Karakorum mountains is poor in species, but essentially transitional and dominated by taxonomically complex and widely distributed groups. Closely related or vicarious species of neighbouring mountains are informally included here for these reasons.

The Karakorum mountains, situated between the high plateaux of East Pamir and West Tibet and bounded by the Kunlun to the north and Himalaya / Hindukush to the the south, are a central continental cross-roads of the Eurasiatic Flora. The tremendous mountain chains, towering in K2 (8611 m), the second highest peak on earth, make up exceptionally sharp boundaries between the Holarctic and (sub-) tropical regions. The Karakorum also constitutes most conspicuous barriers between the Irano-Turanian, the Central Asiatic and the Sino-Himalayan regions with fundamentally different climatic features. On the other hand, the edges of the widely glaciated ridges of the Karakorum link up, as a migration path and filter, the Himalayan and Southeast Tibetan centres of diversification of many „arctic-alpine" floristic elements to other high mountain systems and to the high latitudes of the Holarctic. Centralasiatic elements generally dominate in the cold-arid Karakorum, but flora and vegetation are highly varied altitudinally, and from the periphery to the central ranges as well. A considerable decline of species number from southwest to northeast, linked to a distinct rise of altitudinal distribution limits of many species, is most conspicuous. Most of the rich Sino-Himalayan flora is excluded to the north by the Himalaya main ridge, but a fairly rich West-Himalayan flora is distributed through the Indus gorge to Nanga Parbat and the Southwest Karakorum (Gilgit). The Gilgit area is also a centre of the generally few endemic species of the Karakorum. Upper Chitral and a larger part of the South Karakorum (Yasin, Hunza, Baltistan to Southeast Zanskar) are relatively rich in Himalayan elements, which almost entirely disappear north of the Karakorum main ridge. Irano-Turanian elements are primarily excluded to the east of the ridges at the Afghan and Chitral borders. A reduced set of Irano-Turanian species is widely distributed in the inner valleys of the S Karakorum. Centralasiatic and East Pamirean elements are characteristic to the north and northwest Karakorum, a few species occur disjunct on the south slope, occasionally extending to Ladakh and South Tibet. The distribution areas of some Tibetan (High Asian) elements are separated from the East Pamir to the Tibetan Plateau ("Karakorum gap").

The regional and altitudinal floristic diversity and differentiation (vicarious species) are markedly similar in different taxonomic groups. They are, apparently, predominantly determined by steep climatic gradients. Geological, ecological and evolutionary-systematic aspects of the flora of the Karakorum and the chorology of taxa involved, are discussed. There is some evidence that characteristic actual distribution patterns are connected to palaeoecological environments and events, and they may monitor the history of pleistocene glaciation or even plate-tectonics during the Tertiary.

Vorwort - Preface

Der vorliegende Band ist der Versuch einer kritischen Revision und systematisch-chorologischen Analyse der Flora des Karakorum, Angiospermae, Monocotyledoneae. Die Inventarisierung der Monocotyledoneae des Karakorum-Systems, darunter einige der wichtigsten Futter- und sonstigen Nutzpflanzen, basiert auf der einzigartigen "*La flora del Caracorùm*" (PAMPANINI 1930, 1934) und dem Material sowie den Ergebnissen zahlreicher früherer und nachfolgender Feldforscher und Taxonomen. Ich habe versucht, das trotz aller geländebedingter Schwierigkeiten heute weit umfangreichere Belegmaterial und die Literaturangaben, soweit verfügbar und möglich, kritisch und als Synthese angrenzender Floren zu analysieren.

Ich hatte im Jahr 1986 die Gelegenheit, die Faszination des höchsten und unzugänglichsten Gebirges der Erde, immer noch nahezu einem der letzten "blanks on the map", zu erfahren. Geschlossene Vegetation und selbst einzelne Pflanzen bilden im Großteil des hochariden Karakorum, dessen Oberfläche zu etwa der Hälfte über 5000 m Meereshöhe liegt und in weiten Teilen vergletschert ist, eine seltene Ausnahme. Umsomehr scheint der Karakorum im Herzen Zentralasiens eine "innerkontinentale Grundausstattung" des Lebens zu beherbergen, eine artenarme Flora von engem genetischen Zusammenhalt, deren Glieder außerordentliche Plastizität, Anpassungsfähigkeit und die Möglichkeit weitreichender Radiation besitzen können.

Wissenschaftliche Arbeiten im Karakorum erfordern noch immer volle Expeditionslogistik, wochenlanges Trekking in tief eingeschnittenen Tälern, abenteuerliche Flußüberquerungen und ungesichertes Klettern entlang gigantischer Felswände, nur um die abgelegeneren Gebiete zu erreichen. Die beiden einzigen Straßen über das Gebirge von annähernd der gleichen Fläche, aber fast der doppelten Reliefenergie der europäischen Alpen, der Karakorum Highway über den Khunjerab-Paß und der Kashgar - Lhasa Highway im Osten, sind teure und schwierig zu unterhaltende Bauwerke hoher politischer Sensibilität. Kriege, Nationalitäten- und Grenzkonflikte in Afghanistan, Kashmir, Ladakh und auf dem Aksai Chin-Plateau trugen überdies dazu bei, daß Teile des Karakorum seit dem späten Beginn der Erforschung, die um die Mitte des neunzehnten Jahrhunderts einsetzte, bis heute unzugänglich sind. Andererseits schreitet die Erschließung und ungeregelte Ausnutzung der erreichbaren Ressourcen, die schon bald zum Verschwinden der letzten Waldreste im SW Karakorum führen könnte, auch hier rapide fort.

Danksagung - Acknowledgements

Mein verehrter Lehrer, Prof. Dr. G. Wagenitz (Göttingen), förderte meine Teilnahme an zwei Forschungsreisen nach Zentralasien und ermöglichte die nachfolgenden Auswertungen und die Anfertigung dieser Arbeit am Systematisch-Geobotanischen Institut der Universität Göttingen (GOET). Für seine permanente Unterstützung und Diskussionsbereitschaft möchte ich herzlich danken. Ich danke den Direktoren, Kustoden und Mitarbeitern der folgenden Herbarien: Botanisches Institut Berlin-Dahlem (B), Natural History Museum London (BM), Institut für Kulturpflanzenforschung Gatersleben (GAT), Institut für Botanik Graz (GZU), Helsinki (H), The Royal Botanic Gardens Kew (K), Kyoto (KYO), Botanische Staatssammlung München (M), Naturhistorisches Museum Wien (W), Universität für Bodenkunde Wien (WHB) und Botanisches Institut Zürich (Z) für die freundliche Aufnahme und Unterstützung während meiner Besuche und / oder die freien Ausleihen. Der Plan einer Flora wurde großartig durch Prof. Dr. G. Miehe und Dr. S. Miehe (Marburg) gefördert, die mir ihr Expeditionsherbar, eine der größten Sammlungen aus dem Karakorum, zur Auswertung überließen; herzlichen Dank auch für die zahllosen weiteren Hilfen und Diskussionen. Dr. H. Hartmann (Küsnacht) und Prof. Dr. D. Podlech (München) danke ich für die freundliche Aufnahme und die Verfügbarkeit ihrer reichen Privatherbarien und Erfahrungsschätze; Prof. Dr. R. Rutishauser und Familie danke ich für die Gastfreundschaft in Zürich. Besonders danke ich auch den folgenden Taxonomen für die Hilfe mit ihren jeweiligen Gruppen der Monocotyledoneae: Dr. P. Boyce (Kew), Dr. T. A. Cope (Kew), Dr. J. Cowley (Kew), Prof. Dr. H. Freitag (Kassel), Dr. N. Friesen (Gatersleben / Novosibirsk), Dr. R. Fritsch (Gatersleben), Dr. P. Hanelt (Gatersleben), Dr. F. O. Khassanov (Tashkent), Prof. I. Kukkonen (Helsinki), K. Lewejohann (Göttingen), Prof. Dr. H. Scholz (Berlin), Dr. D.

© Biologiezentrum Linz/Austria; download unter www.biologiezentrum.at

A. Simpson (Kew) und Prof. W. T. Stearn (Kew). Folgenden Sammlern, die wichtiges Material aus dem Karakorum zur Verfügung stellten, danke ich auch für verschiedene weitere Beiträge: A. Bosshard (Zürich), G. Braun (Bonn), R. Hansen (Köln), Prof. Dr. W. Holzner (Wien; danke für alles dort und in Kyoto), Prof. Dr. F. Klötzli (Zürich), Prof. Dr. K. Knorr (Würzburg), M. Kriechbaum (Wien; eine besonders erfolgreiche Zusammenarbeit, auch in der Diskussion schwierigster Formenkreise), M. Nüsser (Berlin), Prof. Dr. J. Poelt (Graz), Dr. U. Schickhoff (Lippetal; auch Literatur). Die wiederholte Durchsicht des Manuskripts besorgten dankenswerterweise K. Adolphi (Roßbach/Wied), K. Kohls (Göttingen), M. Kriechbaum (s.o.) und J. Willers (Göttingen). B. Apelt, U. Döpel und D. Jonas (alle Göttingen) unterstützen mich weiterhin bei Karten und Layout; Dr. U. Winter (Göttingen) bei der Hardware. Dr. U. Hofmann und Prof. Dr. F. G. Schroeder halfen bei vielen Dingen am Institut in Göttingen. Herrn Dr. F. Speta (Linz) danke ich für die rasche und unkomplizierte Drucklegung. Das Florenprojekt hätte nicht ohne die Sach- und Reisebeihilfen der Deutschen Forschungsgemeinschaft unter den Referenztiteln "Karakorum-Flora", "Tibet-Flora", und als Teil des Pakistanisch-Deutschen DFG-Schwerpunktprogramms "Culture Area Karakorum" unternommen werden können. Meine Geländeaufenthalte im Karakorum und Tibet wurden zusätzlich von der Max-Planck-Gesellschaft und Academia Sinica unterstützt. Prof. Huang Rong-Fu (Xining), Prof. Dr. M. Kuhle (Göttingen) und Prof. Xu Daoming (Lanzhou) danke ich stellvertretend für die gesamten Arbeitsgruppen der Expeditionen für die vertrauensvolle und erfolgreiche Kooperation im Gelände. Meinen Eltern danke ich herzlich für die langjährige Unterstützung, meinen Kindern Joshua und Marco, ohne deren Hilfe die Arbeit eventuell hätte früher beendet werden können, für ihre Geduld.

Abkürzungen, Symbole und Anordnung - Abbreviations, symbols and arrangement

Die Abkürzungen für Autoren folgen weitgehend BRUMMITT & POWELL (1992, Authors of Plant Names, Kew), für Bücher und Zeitschriften B-P-H, B-P-H/S (Botanico-Periodicum Huntianum, LAWRENCE & al. [ed.] 1968, Pittsburgh; BRIDSON & SMITH [ed.] 1991, Pittsburgh), für Herbarien Index Herbariorum (HOLMGREN & al. 1990, ed. 8, 1. The Herbaria of the World, New York). Abkürzungen allgemeinen Gebrauchs wie SI-Einheiten sind in der folgenden Liste ebenfalls nicht enthalten. Familien, Gattungen, Arten und Unterarten sind alphabetisch angeordnet, Bastarde am Ende der jeweiligen Gattung, Gattungsbastarde am Ende der Familie. Der Aufbau der systematischen Aufzählung folgt einem einheitlichen, unten erläuterten Schema, das bei kultivierten Pflanzen [•] und zusätzlich erwähnten, bislang nicht im Karakorum nachgewiesenen Sippen [*, kleingedruckt] um einige Elemente reduziert ist. In einem vertretbar erscheinenden Ausmaß wurde die Original-Information von Herbarium-Etiketten und aus der Literatur (außer von historisch interessanten Belegen und Schreibweisen sowie Typen) abgekürzt und standardisiert.

The following list does not include abbreviations of authorities, books and journals, herbaria and abbreviations of general usage, as SI-units. For the first I have followed BRUMMITT & POWELL (1992, Authors of Plant Names, Kew), largely, for the second B-P-H, B-P-H/S (Botanico-Periodicum Huntianum, LAWRENCE & al. [ed.] 1968, Pittsburgh; BRIDSON & SMITH [ed.] 1991, Pittsburgh), for the third Index Herbariorum (HOLMGREN & al. 1990, ed. 8, 1. The Herbaria of the World, New York). The last should be readily comprehensible. Families, genera, species and subspecies are arranged alphabetically, hybrids at the end of the genus, infrageneric hybrids at the end of the family. Species records from the Karakorum are given in a uniform scheme, which is explained below. The data set is reduced in cultivated plants [•], and additional species [*, printed in small type], which are not yet reported from the Karakorum. Locality references and the originial information from herbarium tickets (except for type- and historically interesting information) are standardised to a certain degree and shortened by dropping of expletives.

I. Standardabkürzungen - General abbreviations

Afgh.	Afghanistan
alp.	alpine
Baluch.	Baluchistan
c.	circa, about
C.	central
Centr.As.	Central Asiatic element
cf.	confer, similar to
coll.	colline
Cosmopol.	Cosmopolite
Dzung.	Dzungaria
E	east
E Asiat.	East Asiatic element
E Pamir.	East Pamirean element
Endem.	Endemic, confined to a small distribution area
Euras.	Eurasiatic element
Euro-Sib.	Euro-Siberian element
excl.	excluding
fig.	figure
Gl.	glacier
Holarct.	Holarctic element
Ir.-Tur.	Irano-Turanian element
KKH	Karakorum Highway
leg.	legit, collected by
Medit.	Mediterranean element
mont.	montane
Mts.	Mountains
N	north
NWFP	North West Frontier Province (Pakistan)
P.	pass (La, Davan, An)
Palaeotrop.	Palaeotropical element
Pantrop.	Pantropical element
pl.	plate
p.p.	in part (pro parte)
Rd.	road
Rv.	river (He, Darya)
S	south
Sino-Him.	Sino-Himalayan element
s.n.	without number (sine numero)
S Tibet.	South Tibetan element
subalp.	subalpine
subniv.	subnival / high alpine
subtrop.	subtropical
Sud.-Sind.	Sudano-Sindean element
temp.	temperate
Tibet.	Tibetan element
trop.	tropical
veg.	vegetative specimen (thought to be distinctive)
Vy.	valley (Chu, river basin)
W	west
W Centr.As.	West Central Asiatic element
W Himal.	West Himalayan element
W Pamir.	West Pamirean element
yg.	Young specimen (thought to be distinctive).
!	Specimen seen by the author
?	Ambiguous data (illegible or doubted)
[ ]	Additional comments by the author
'	(in original or type information) feet: 1'= 0.3048 m
-	(with blanks) from - to, in-between
+	(before collecting number): provisional number
•	Cultivated species (potentially)
*	Additional species not reported from the Karakorum

II. Anordnung der Nachweise - Arrangement of records

Scheme of species records:

1. Current number. Name of species AUTHOR, reference to original publication
2. [synonyms] *Synonym* AUTHOR year of publication
3. **Ic.:** Illustrations (optional, if available preferably of good access and quality).
4. **[Area Subarea:]** Records of the taxon from the Karakorum) **(Unloc.:** for untracable localities).
5. **A**: Records from adjacent areas. (optional).
6. **D**: Total distribution. **Map:** Distribution map (optional).
7. **E**: Ecology (total altitudinal range in Karakorum, altitudinal belt, regional frequency. Habitat).
8. **N**: Additional Notes.

© Biologiezentrum Linz/Austria; download unter www.biologiezentrum.at

Citation of specimens:

[locality] [altitude] [, date], [*reference*].
One or more components of this record form may be missing. Records with identical elements are connected with semicolon [;].

Locality: in descending order separated by commas, if consisting of more than one component. Symbols as defined above.

Altitude: in metres above sea level, rounded in 10 metre intervals. Values in feet were converted to metres by multiplication with 0.3048. Altitudinal ranges are cited [from-to]. If the originally given altitudinal range seems to be very inaccurate (ranging more than 400 m in a single herbarium specimen), or in any other way unconfirmed, the altitude is given in brackets [( )], dubious altitudes with question mark [?].

Date: is only given in records without collecting number or when of special interest. Citation form: Year-Month-Day, if a from - to record: [/] (example: 1856-07-15/08-05 = July 15th to August 8th, 1856).

Reference: the reference form is as follows:
[*collector*] [*collecting number*] [(HERBARIUM; LITERATURE)]. Specimens seen by the author are indicated with exclamation mark [!].

Examples of localities:

Ganto P. W :	West of Ganto La (West-facing slope)
K2-N Gl. W :	West of K2-North glacier (East-facing slope)
Muztagh Vy. E :	Eastern (flanks of) Muztagh valley (West-facing slope)
Doko - Gon :	Between Doko and Gon.

Example of a record:

(*Carex atrofusca*):

[Sassir - Murgai] (4570-5180 m), 1848-08-28, *T.Thomson* (CLARKE 1898; K! **type** *C. hypsobates* NELMES 1940).

The specimen of *Carex atrofusca* seen at Kew (K!), bearing the collecting date of *Thomas Thomson*, a rather inaccurate locality ("Nubra") and altitude "15000-17000 feet" (in brackets: amplitude > 400 m), was collected between Sassir and Murgai (in square brackets; here: according to THOMSON 1852), cited by CLARKE 1898, and taken as the (holo)type of *Carex hypsobates* by NELMES (1940).

III. Wichtigste Quellen - Main sources of records

General floras which do not, or only to a minor part of their area, cover the Karakorum, or not giving definite localities, are cited only under certain circumstances and abbreviated as follows:

Enum.Nepal	An Enumeration of the Flowering Plants of Nepal
Fl.Bhutan	Flora of Bhutan
Fl.Brit.India	Flora of British India
Fl.Eur.	Flora Europaea
Fl.Sin.	Flora Reipublicae Popularis Sinicae
Fl.USSR	Flora of the USSR

© Biologiezentrum Linz/Austria; download unter www.biologiezentrum.at

Standard floras relating to the Karakorum or adjoining areas are cited and abbreviated as follows:

Ann.Cat.Pak.	R.R.STEWART 1972: Flora of West Pakistan. Annotated Catalogue.
Fl.Desert.Sin	Flora in Desertis Reipublicae Populorum Sinarum
Fl.Iran.	Flora Iranica
Fl.Pak.	Flora of (West) Pakistan
Fl.Tadzh.	Flora Tadzhikskoy SSR [Flora of the Tadzhik SSR]
Fl.Xizang.	Flora Xizangica
Pl.As.Centr.	Plantae Asiae Centralis

The abbreviation without volume number is cited for records from these floras, except for *Fl.Pak.* which covers most of the flora of the Karakorum. Specimens not seen by the author and cited in *Fl.Pak.* are given only by herbarium reference. *Pl.As.Centr.*, which includes the Karakorum N slope, are repeated. Records from *Fl.Iran.* and *Fl.Tadzh.*, which cover areas adjoining to, but not overlapping with the Karakorum as defined here (Chitral, Swat and Pamir), are generally not repeated, but included in the distribution maps. *Fl.Xizang.*, the only flora that is at present complete, does not include the Karakorum itself nor does it give definite localities. *Fl.Desert.Sin.* has been consulted for illustrations only.

Regional floras are:

HEMSLEY 1902	The Flora of Tibet or High Asia
FEDTSCHENKO 1903-1915	Flore du Pamir
PAMPANINI 1930	La flora del Caracorùm
PAMPANINI 1934	Aggiunte alla flora del Caracorùm
PODLECH & ANDERS 1977	Florula des Wakhan
ASWAL & MEHROTRA 1994	Flora of Lahaul-Spiti

Local floras, expedition reports and other contributions as major other sources of literature information from the Karakorum and immediately neighbouring areas are:

HENDERSON & HUME 1873	(Ladakh, E Karakorum, Kunlun, Kashgaria)
STEWART 1916	(Ladakh)
OSTENFELD 1922	(E Pamir, N Karakorum, Tibet)
DOLK 1929	(W Karakorum)
SCHMID 1932	(Ladakh, E Karakorum, Kunlun, Kashgaria)
WENDELBO 1952	(Chitral: Tirich Mir)
GILLI 1957	(CS Karakorum)
KITAMURA 1960	(Karakorum, Swat, Hazara)
KITAMURA 1964	(Afghanistan)
WEBSTER & NASIR 1965	(CS Karakorum)
HARTMANN 1966	(CS Karakorum)
GREY-WILSON 1974	(Wakhan)
BILLIÉT & LEONARD 1986	(Ladakh)
DICKORÉ 1991	(CN & N Karakorum, Kunlun, W Kashgaria)

1 Einleitung - Introduction

Die letzte und einzige Flora des Karakorum, PAMPANINI (1930, 1934), ist eine sehr bemerkenswerte Arbeit, die nicht nur das floristische Wissen seiner Zeit zusammenfaßt. Sie enthält darüber hinaus die Reiserouten aller Sammler, die bis zu diesem Zeitpunkt in das abgelegene Gebirge vorgestoßen waren. Mit einer gut reproduzierbaren Nomenklatur und Sippenauffassung versucht PAMPANINI (1930) auch bereits eine geoökologische Gliederung und altitudinale Zonierung, die allerdings auf dem damals noch nicht sehr umfangreichen Datenmaterial beruht. Nach „*Flora of Tibet*" (HEMSLEY 1902) und „*Flora Pamira*" (FEDTSCHENKO 1902-1915) ist PAMPANINIs „*La flora del Caracorùm*" die letzte handliche und abgeschlossene Flora für ein geobotanisch definiertes Gebirgssystem Hochasiens. Obwohl PAMPANINI (1930, 1934) eine gute Basis bildet, verlangt das in jüngerer Zeit angesammelte Material nach einer kritischen Überarbeitung.

Moderne Floren, deren Gebiet Teile des Karakorum einschließen oder daran angrenzen sind *Flora Iranica*, *Flora of Pakistan*, *Flora Tadzhikistana*, *Plantae Asiae Centralis*, *Flora Xizangica* und *Flora Sinica*. Alle bis auf *Flora Xizangica* sind unvollendet, die meisten sind monumental und bestehen aus zahlreichen Faszikeln. Die für den Karakorum relevante botanische Information muß aus der gewaltigen Menge des publizierten Materials extrahiert werden und bleibt zu einem Großteil redundant oder inkonsistent. Der Karakorum bildet eine der markantesten natürlichen und politischen Grenzen Asiens, gleichfalls aber auch für die jeweils adaptierten unterschiedlichen taxonomischen Konzepte. Da die meisten der modernen Floren nationale Projekte sind, sind unterschiedliche Benennungen und unnötige Neubeschreibungen vermeintlich neuer Sippen jenseits politischer Grenzen häufig.

Wegen der zentralen Lage des Karakorum und der weitgehend unzusammenhängenden botanisch-systematischen Bearbeitung benachbarter Gebiete wurde der geographische Rahmen in der vorliegenden Untersuchung möglichst weit gefaßt. Eine größere Anzahl von Taxa, die bisher nicht aus dem Karakorum nachgewiesen sind, wurde mitberücksichtigt. Diese umfassen in angrenzenden Gebieten verbreitete Sippen ("to be expected"), häufige Fehlbestimmungen, die oft auch zu nah verwandten und vikariierenden Sippen zu rechnen sind (misidentifications and closely related / vicarious taxa), und ungeklärte Verwandtschaftskreise und Nomina ("poorly understood"). Obwohl somit ein großer Teil des Arteninventars benachbarter Gebirge (W Kunlun Shan, E Pamir, NE Hindukush, W Himalaya, W Tibet) hier zusätzlich berücksichtigt wird, ist die Auswahl dieser Taxa künstlich und kann nicht als repräsentativ gelten. Beabsichtigt ist allerdings die Andeutung eventueller floristischer Beziehungen zu Nachbargebieten und offener Probleme.

Generell macht die Flora des Karakorum einen außerordentlich kohärenten Eindruck. Hochgradig uniformierende Konvergenz bei gleichzeitig hoher intraspezifischer Variabilität, aber auch interspezifischer Kontakt und Genaustausch, Grenzfälle der Artbildung und des Artbegriffs, scheinen in der lebensfeindlich kalt-ariden und zentralkontinentalen Umgebung des Karakorum eher die Regel denn Ausnahme. Als schwierig bekannte Großgattungen wie *Calamagrostis*, *Elymus*, *Festuca*, *Poa*, *Puccinellia*, *Stipa*, dominieren in der Flora des Karakorum weit über die vereinzelten, taxonomisch isolierteren Endemiten. Exakte Artdefinitionen wären oft, wenn überhaupt, nur durch cytologische oder genetische Untersuchungen zu fixieren. Die schwierige Verfügbarkeit von (Lebend-) Material oder die Merkmalsarmut und mangelnde morphologische Korrelation können aber auch die Ergebnisse dieser Zukunftsaufgaben begrenzen. Ein vergleichsweise profanes, aber evidentes Problem stellte für die vorliegende morphologische Bearbeitung bereits das Herbarmaterial aus dem Karakorum dar, das auch unter günstigen Sammelbedingungen zu einem Großteil vegetativ, verkümmert oder verbissen ist.

Ungelöste taxonomische Probleme bieten weiterhin vor allem Repräsentanten Irano-Turanischer Großgattungen, die den Karakorum nur mit einzelnen Vertretern erreichen (*Eremurus*, *Gagea*). Welche Taxa im Karakorum vorkommen, kann vom Arealrand her oft nicht einwandfrei geklärt werden. Die Zahl der in der Literatur für den Karakorum angegebenen Arten übersteigt hier u.U. die Zahl der Belege.

Aus den angegebenen Gründen ist die vorliegende Flora in weiten Teilen in Diskussionsform gehalten. Zwar konnte in vielen Fällen Typusmaterial eingesehen, dessen exakter Status jedoch häufig nicht geklärt

© Biologiezentrum Linz/Austria; download unter www.biologiezentrum.at

werden. Die Synonymie ist daher auf die für das Gebiet wichtigen und allgemein akzeptierten Nomina beschränkt; wichtige neue Synonyme sind entsprechend gekennzeichnet. Typusbelege werden generell nur zitiert, wenn sie aus dem Karakorum oder angrenzenden Gebieten stammen. Literaturangaben ohne verfügbares korrespondierendes Herbarmaterial werden, soweit möglich, übernommen bzw. interpretiert. Ich habe generell versucht, ein möglichst konservatives und relativ weites Artkonzept anzuwenden. Dieses beruht auf morphologischen Differentialdiagnosen, in einigen Fällen auch auf Beobachtungen in lebenden Populationen. Die Artabgrenzung wird, soweit möglich, durch ökologische und chorologische Konzepte gestützt.

Die Schreibweise geographischer Namen, außer von Nationalstaaten, erfolgt in der vorliegenden Arbeit grundsätzlich in einer standardisierten englischen Form, der taxonomische Teil (Systematische Aufzählung - Systematic Enumeration) ist ganz auf Englisch abgefaßt, um das Problem der zahllosen existierenden Varianten und Ansätze möglichst nicht weiter zu verschärfen. Lediglich der sprachlich korrekten Schreibweise "Karakorum" (= black gravel, nach dem im Bereich des Karakorum P. anstehenden karbonischen Schiefergestein), homonym allerdings mit der historischen Hauptstadt der Mongolei, wurde der Vorzug gegenüber dem eindeutigen, aber in der englischen Literatur auch nicht durchgängig verwendeten "Karakoram" gegeben. Russische Namen, mit Ausnahme der gebräuchlichen Autorennamen, sind in der einfachsten englischen Form transkribiert.

2 Geographie - Geography

2.1 Abgrenzung des Karakorum - Delimitation of the Karakorum

Die vorliegende Arbeit umfaßt das Karakorum-System und angrenzende Gebiete wie oben definiert (Karte 1 - map 1, pp. ix-xi). Die Abgrenzung und Untergliederung des Karakorum basiert auf der Gliederung von PAMPANINI (1930). Änderungen sind unten angegeben.

Abgesehen von verschiedenen abweichenden Systemen und Möglichkeiten (z.B. Karakoram Map, Swiss Foundation for Alpine Research 1990), ist die geographische Abgrenzung des Karakorum im N durch die Längstäler von Yarkand und Karakash und im S durch den Verlauf der Flüsse Gilgit und Indus klar definierbar. Aus praktischen Erwägungen wird hier die jeweils direkt gegenüberliegende Talseite, ausschließlich der größeren Seitentäler, mitberücksichtigt:

1. Die jeweilige Talseite, an der eine Pflanze gesammelt oder beobachtet wird, ist relativ zufällig und hängt von der Erreichbarkeit des Ortes ab. Viele der großen Täler des Karakorum sind nur an einer Seite zugänglich und müssen häufig gequert werden. Die Flußläufe sind zudem oft unstabil. Würde der Flußlauf oder die Tiefenlinie als Grenze gewählt, so müßte z.B. im Upper Indus Vy. Leh ein- und Skardu mit einer ähnlichen Flora im Lower Indus Vy. ausgeschlossen werden, weil die Orte zufällig auf verschiedenen Flußseiten liegen. Praktisch unmöglich wäre eine solche Trennung in den wenig bekannten Tälern der Karakorum N-Seite.

2. Selbst in größeren Höhen über dem Talgrund sind die Floren gegenüberliegender Talseiten einander offenbar ähnlicher als die gegenüberliegender Paßseiten. Die großen Täler haben ein eigenes Klima. Daher verlaufen auch die Vegetations-Höhengrenzen selbst E-W gerichteter Täler auf annähernd derselben Höhe. Die Asymmetrie drückt sich im ariden Gebiet überwiegend in einer höheren Artenzahl der Nordexposition aus (DICKORÉ 1991).

3. Die südexponierten Talhänge sind generell wesentlich trockener als die nordexponierten. Im extremen Fall der Täler des N Karakorum (Yarkand, Karakash), sind die südexponierten Hänge nahezu vegetationsfrei. Der Löß der Kunlun Shan N-Abdachung fehlt hier auf beiden Talhängen. Da die wenigen Arten der Kunlun Shan S-Seite ebenfalls typischer für die Flora der inneren Ketten sind, ist der Einschluß der Kunlun Shan S-Abdachung in den Karakorum auch floristisch und ökologisch gerechtfertigt.

4. Die Himalaya-Hauptkette spielt im S eine noch entscheidendere Rolle, indem sie den größten Teil der hygrophilen Sino-Himalayischen Monsun-Flora begrenzt. Die Hauptkette ist jedoch im Bereich des Indus-Durchbruchtales und im Zoji P. tief eingeschnitten. Daher kann eine verarmte Himalayische Flora in den SW Karakorum eindringen. Als Begrenzung wurde hier ein Kompromiß gewählt, der einen offenbar

© Biologiezentrum Linz/Austria; download unter www.biologiezentrum.at

charakteristischen erweiterten W Himalayischen Artensatz einschließt, aber die Hauptmasse der artenreichen Sino-Himalayischen Flora der Himalaya S-Seite ausschließt.

Die E-Grenze des Karakorum sensu PAMPANINI (1930) ist künstlich und schließt einen ausgedehnten Teil des Tibetanischen Plateaus ein. Diese Grenze kann nicht natürlicher gefaßt werden, es sei denn, man schließt den gesamten tibetanischen NE-Teil des Karakorum aus. Um die Vergleichbarkeit zu erhalten und den Übergang zum Tibetanischen Plateau zu demonstrieren, wurde diese Grenze jedoch nur leicht verändert und schließt hier das Aksai Chin / Lingzhi Tang-Plateau, etwa entlang der Linie des "Indian claim" auf den Karten, das Changchenmo Vy. und den W Pangong Lake ein.

Im W kann eine natürlichere Abgrenzung durch den Einschluß des gesamten Gilgit-Einzugsgebietes erreicht werden. Ghizar, Yasin und Ishkoman bilden den Übergang zum Hindukush-System, sind dem Karakorum aber auch floristisch ähnlicher als dem westlich angrenzenden Gebiet, auch wenn sich ein gewisser Irano-Turanischer Einfluß bemerkbar macht. Aus ähnlichen Gründen wurde auch das bei PAMPANINI ebenfalls nicht berücksichtigte Übergangsgebiet zum Pamir-System nördlich des Khunjerab P. (Mintake, Taxkorgan) eingeschlossen. Das Mustagh Ata-Massiv steht etwas abseits und vermittelt zwischen Karakorum, Pamir und dem Kunlun Shan-System (King Ata Tagh, Kongur Shan). Eine hinreichende Ähnlichkeit zur Flora des NW Karakorum rechtfertigt auch hier den Einschluß.

Administrativ umfaßt der Karakorum Teile der Xinjiang Autonomous Region (Xinjiang Uygur Zizhiqu / Sinkiang) von China, der Gilgit and Baltistan Prefectures der Northern Areas Pakistans und des Jammu & Kashmir State Indiens. Im W grenzt das oben definierte Gebiet an den Chitral State Pakistans, den Wakhan Corridor (Badakhshan Province) Afghanistans und den Murghab District Tadzhikistans (frühere Sowjetunion); im SE an Tibet oder die Xizang Autonomous Region Chinas. Die nationalen Grenzen sind ungünstigerweise streckenweise undefiniert, umstritten oder bilden sensible Waffenstillstandslinien. Die Bezeichnung der politischen Grenzen im Text und auf den Karten sind nicht autoritativ.

2.2 **Topographie** - Topography

Der Karakorum, wie hier definiert, liegt etwa zwischen 33° - 38° N und 73° - 80° E. Er umfaßt ein Gebiet von etwa 180 000 km^2, annähernd die Ausdehnung der europäischen Alpen (200 000 km^2). Da der Karakorum seinerseits von extremen Hochgebirgen umgeben ist, ist die geoökologische Abgrenzung vergleichsweise schwierig. Das Karakorum-System verbindet die Plateaus von Tibet und Pamir. An das Westende der Karakorum-Hauptkette schließt sich der in NE - SW-Richtung verlaufende Hindukush an. Im N und S begrenzen die ± parallel verlaufenden Systeme des W Kunlun Shan bzw. des W Himalaya den Karakorum.

Das Karakorum-System besteht aus einer Serie generell NW - SE verlaufender Hochgebirgsketten von etwa 600 km Länge auf einer Breite zwischen 200 und 400 km. Im E scharen die Ketten weit und tauchen in das Tibetanische Plateau ein, einem vergleichsweise ebenen Tafelland zwischen 5000 und 6000 m Meereshöhe mit nur wenigen isolierten Bergmassiven von wesentlich größerer Höhe. Die Hauptachse des Karakorum beschreibt einen flachen nach S geöffneten Bogen, der im W auf der Höhe von Chitral nach SW schwingt und in den Hindukush übergeht. Die Ketten des N Karakorum bilden einen gegenläufigen Bogen, der im NW mit der Mustagh Ata-Gruppe an die Gebirge des King Ata Tagh und Kongur Shan (W Kunlun Shan) und die Sarykol-Kette des E Pamir anschließt.

Der größte Teil des Karakorum ist ein Gebiet maximaler Reliefenergie, das in dieser Flächenausdehnung selbst den zentralen Himalaya übertrifft. Ein Meer von 6000-8000 m hohen Gipfeln und steile Schluchttäler, eingeschnitten bis auf unter 2000-3000 m Meereshöhe, charakterisieren den Zentral-Karakorum. Vier Gipfel erreichen mehr als 8000 m, K2 (Chogori Feng, Mt. Godwin-Austen, 8611 m), der zweithöchste Berg der Erde, Gasherbrum (8068 m), Broad Peak (8047 m) und Hidden Peak (8035 m). Mehr als 15 größere Gruppen und zahllose Einzel-Peaks überragen 7000 m. Unter den prominentesten dieser Gipfel sind Rakaposhi (7754 m), Haramosh (7397 m), Disteghil Sar (7989 m), Masherbrum (7821 m), Saltoro Kangri (7742 m), Saser Kangri (7672 m) und, etwas abseits im NW, Mustagh Ata (7546 m). Einige

© Biologiezentrum Linz/Austria; download unter www.biologiezentrum.at

der höchsten Gipfel, die den Karakorum umgeben, sind Pik Kommunizma / Pik Kaufmann (7495 m) und Pik Lenina (7134 m) im Pamir, Kongur Shan (7719 m) und Mustagh (7281 m) im Kunlun Shan, Tirich Mir (7708 m) und Noshaq (7349 m) im Hindukush, Nanga Parbat (8126 m), Nunkun (7135 m) und Shilla (7026 m) im Himalaya.

Der tiefste Punkt des Karakorum an der Einmündung des Gilgit in den Indus (1300 m, bzw. Bunji 1270 m) liegt zwischen den nur ca. 100 km von einander entfernten Gipfeln von Nanga Parbat und Rakaposhi. Talböden mit breiten alluvialen Flußterrassen reichen entlang des Indus im S von unter 1500 m bis über 4000 m und erstrecken sich entlang Yarkand und Karakash im N zwischen 3000 und über 5000 m Meereshöhe.

Der Zentral-Karakorum umfaßt grob die Hauptkette zwischen Khunjerab P. (4703 m) und Karakorum P. (5575 m). Mit Ausnahme des Shimshal P. (4735 m) unterschreitet der Kamm der Hauptkette auf einer Strecke von 250 km kaum 6000 m Meereshöhe. Der Karakorum bildet die Wasserscheide zwischen dem Indus-Einzugsgebiet und dem internen Entwässerungsgebiet Zentalasiens (Yarkand Vy., Karakash Vy.). Die NW-Grenze des Karakorum entspricht der Wasserscheide zum Einzugsgebiet des Amu Darya (mittelasiatisches internes Entwässerungsgebiet). Teile des NE Karakorum, der größte Teil NW Tibets (Changtang, Qiangtang) und ein Teil von Rupshu (S des Indus) sind abflußlose Hochgebirgsbecken. Die Pässe der kontinentalen Wasserscheide befinden sich im N Karakorum. Die rückschreitende Erosion der großen Indus-Zuflüsse, Hunza im W und Shyok im E, hat die Karakorum-Hauptkette tief durchschnitten. Die Oberläufe dieser Flüsse (Batura, Khunjerab, Shimshal; Upper Shyok, Depsang, Changchenmo) repräsentieren daher die geologische Nordseite des Karakorum (Aghil Range).

2.3 **Geographische Regionen** - Geographical divisions

Die Regionalisierung des Karakorum in größere Talschaften folgt prinzipiell PAMPANINI (1930), mit verschiedenen durch die unterschiedliche Abgrenzung und das verfügbare differenziertere Material induzierten Abweichungen. Einige der größeren Teilgebiete PAMPANINIs wurden in Einheiten vergleichbarer Größe unterteilt. So wurde sein "Valle del Hunza": Hunza, Batura, Khunjerab und Shimshal, "Valle del Indo": Skardu und Leh, "Valle del Sciàiok": Lower Shyok, Shyok und Upper Shyok, "Versante settentrionale": Yarkand, Upper Yarkand, Braldu, K2-North, Shaksgam und Upper Karakash. Die reichen, neueren Sammlungen erlauben eine feinere Unterteilung im N und W auch auf floristisch-chorologischer Grundlage, während das Material aus dem SE Karakorum bis heute unterrepräsentiert ist.

Die geographische Gliederung des Karakorum und angrenzender Gebiete ist allein als Referenzsystem gedacht. Die abgegrenzten Sektoren sind nicht notwendigerweise floristisch homogen. Hunza z.B. umfaßt einen feuchten SE- (Nagar) und einen trockenen NW-Teil. Charakteristische Verbreitungsmuster erstrecken sich oft auch etwas über Pässe. Die untersuchten Sammlungen ergaben etwa, daß die Flora eines kleinen Gebietes SW des Khunjerab P. typisch zentralasiatisch ist, oder daß der östlichste Teil des Karakash-Tales die Tibetanische Flora des Aksai Chin beherbergt. Dieses sind jedoch phytogeographische Ergebnisse, die nicht a priori als Referenzsystem genutzt werden können. Prinzipiell erwies sich jedoch die auf PAMPANINI aufbauende geographische Gliederung auch zur Darstellung chorologischer Zusammenhänge als gut geeignet. In relativ wenigen Fällen erschweren größere Paßplateaus (z.B. Shimshal [Pamir] P. und Thalle P.) oder ungenau angegebenene Fundumstände die exakte Lokalisierung und Zuordnung von Belegen oder Literaturangaben. Gegen die Anwendung eines Gitternetzes spricht die geringe und ungleichmäßige Durchforschung sowie die extrem gebirgige Natur des Karakorum, die die Zuordnung eines Nachweises zu einer Talflanke meist wesentlich sicherer und aussagekräftiger macht.

Ortsnamen sind im Karakorum und weiten Teilen Zentralasiens ein permanentes Problem, da unzählige Namen, Sprachen, Varianten und Synonyme selbst in den fast unbesiedelten Gebieten existieren. Viele Lokalitäten sind lediglich "camping grounds" oder "base camps" ohne irgendwelche Bauwerke und mit wechselnder Bedeutung und Repräsentanz auf verschiedenen Karten. Ein weiteres Problem ist die asiatische Eigenart, daß häufig die Täler an den gegenüberliegenden Seiten eines Passes den gleichen Namen tragen. In der Schreibweise der Ortsnamen habe ich eine vorsichtige, aber nicht durchgängig mögliche

© Biologiezentrum Linz/Austria; download unter www.biologiezentrum.at

Standardisierung versucht. Herbarmaterial sollte immer mit möglichst exakten Koordinaten und Meereshöhen versehen werden.

Als weitere geographische Referenz werden für die systematische Übersicht sechs größere Unterteilungen des Karakorum eingeführt: CN, CS, N, W, S und E (Central North, Central South, North, West, South, East). Auch deren Abgrenzungen sind, wie die der angrenzenden Gebiete (Karte 1 - map 1), rein deskriptiv, aber mit dem Versuch, die Arten phytogeographischen Regionen und Verbreitungsmustern zuzuordnen, verbunden.

Auch bei den angrenzenden Gebieten bilden politische Grenzen problematische und oft unzureichende Einheiten. Hier wird Swat auf das Einzugsgebiet des Swat-Flusses (einschließlich Dir) beschränkt. Hazara schließt die direkt zum Indus entwässernden Täler und das Kaghan Vy. ein, das Gebiet indusaufwärts wird als Chilas (Diamir, Chilas Agency) abgegrenzt. Astor ist ein gut definiertes Talsystem, politisch jedoch ein Teil von Gilgit. Deosai (einschließlich Shingo Vy.), Dras, Suru (einschließlich Wakha Vy.) und Zanskar (Zaskar) umschließen ebenfalls relativ gut abgegrenzte Talschaften, werden in der Literatur aber häufig abweichend definiert. Rupshu (abflußloses Gebiet, Upper Sutlej Vy. und Hanle Vy.) ist in der hier verwendeten Umgrenzung geographisch sehr heterogen, aber durch eine einheitliche tibetanische Übergangsflora gekennzeichnet. Azad Kashmir (Muzaffarabad / Pakistan) und Kashmir (Jammu & Kashmir / Indien), getrennt durch eine militärstrategisch begründete, relativ unnatürliche Waffenstillstandslinie, werden zusammengefaßt. Die hier verwendeten Grenzen zwischen Kashmir, Himachal Pradesh und Uttar Pradesh entsprechen weitgehend denen der indischen Verwaltungseinheiten, mit der Ausnahme, daß die kleinen Teile von Himachal Pradesh N der Himalaya-Hauptkette Zanskar (Bara Lacha P. N) bzw. Rupshu (Parang P. N) zugeschlagen werden. Die geographischen Bezeichnungen werden hier in der definierten Weise benutzt und nicht in deren üblichen und oft weit differierenden Bedeutungen.

3 **Geologie und Pedologie** - Geology and Pedology

3.1 **Tektonik** - Tectonics

Die komplexe Geologie und Tektonik des Karakorum und angrenzender Gebirgssysteme ist in weiten Teilen immer noch unzureichend bekannt. Es kann jedoch auf eine hervorragende moderne Synthese (SEARLE 1991) verwiesen werden, die die Grundlage der folgenden kurzen Zusammenfassung bildet. GANSSER (1964) gibt eine Übersicht für das Himalaya-System.

Die Orogenese des Karakorum ist eine direkte Folge der äquatornahen Kollision der Indischen Kontinentalplatte im frühen Eozän (vor ca. 50 Ma) und deren mit einer Geschwindigkeit von ca. 10-20 mm/a andauernden Subduktion unter die Asiatische Plattengruppe. Die Dicke der Kontinentalkruste im Bereich von Karakorum, Himalaya und Tibet beträgt ca. 50-80 km, d.H. etwa die doppelte normale Dicke. Die Hebung des Karakorum dauert mit einem abzüglich der Erosionsrate auf 0,8-1,6 mm/a geschätzten Betrag an.

Zwei größere Nahtzonen südlich des Karakorum markieren den Schluß der Tethys-Geosynklinale, bzw. den Nordrand der Indischen (Indus Suture Zone) und den Südrand der Asiatischen Platte (Shyok Suture Zone, Main Karakoram Thrust). Der zwischen beiden Plattenrändern eingeschlossene Inselbogen (Kohistan-Ladakh Island Arc) ist durch einen im Bereich von Nanga Parbat - Haramosh unterkeilten Zahn der Indischen Platte (Nanga Parbat Syntaxis) unterbrochen (Kohistan Batholith Terrane, Ladakh Batholith Terrane). Im Nordosten begrenzt die Karakorum-Verwerfung (Karakoram Fault) den Karakorum-Batholithen gegen Tibet, das Changtang-Becken (Qiangtang Terrane) nördlich und S Tibet (Lhasa Terrane) südlich der Pangong Nahtzone (Bangong-Nujiang Suture). Die Karakorum-Verwerfung hat, trotz ihrer Ausmaße und erheblichem Lateralversatz, offenbar keinen Einfluß auf die Zone größter Massenerhebung im Zentral-Karakorum, die sie ohne erkennbare Konsequenz durchzieht (Karte 2 - map 2).

Die Durchbruchsschluchten des Indus (Nanga Parbat Syntaxis) und Tsangpo/Brahmaputra (Namcha Barwa Syntaxis) markieren die Eckpunkte der Einzahnung der Indischen Platte am W- und E- Ende des Himalaya.

© Biologiezentrum Linz/Austria; download unter www.biologiezentrum.at

Die Auffaltung des ostwärts ausweichenden Tibetanischen Plateaus erfolgt(e) nördlich dieser analogen, durch das S Tibetanische Verwerfungssystem (Karakoram-Jiale Fault System) verbundenen Strukturen. Als südliche Begrenzung der Himalaya-Auffaltung entsprechen die Hazara Syntaxis und die Assam Syntaxis der Haupt-Unterschiebungsgrenze (Main Boundary Thrust) einander.

Details der tektonischen Abgrenzung des Karakorum gegen den afghanischen Hindukush (Reshun Fault) und den Pamirknoten im W, sowie den Kunlun Shan im N und E (Kunlun Fault, Altyn Tagh Fault) müssen als weitgehend unbekannt gelten. Eine erste Übersicht über die Stratigraphie des N Karakorum und Kunlun Shan gibt DE TERRA (1932).

3.2 **Stratigraphie** - Stratigraphy

GATTINGER (1961) und SEARLE (1991) bieten geologische Karten, die für eine nähere Untersuchung von Zusammenhängen zwischen der geologischen Unterlage und der Vegetationsbedeckung und Florenausstattung genutzt werden können. Korrelationen sind jedoch aus verschiedenen Gründen sehr schwierig. Die anstehenden Gesteine sind außerordentlich vielfältig und wechseln oft kleinräumig. Mehr oder weniger kalkhaltige, kaum metamorphe Sedimentgesteine sind aufgrund der jungen Orogenese auch in engem räumlichen Kontakt der zentralen Granitplutone erhalten. Gneise (K2 Gneiss), Granite und kaum metamorphe, vorwiegend mesozoische Sandsteine und Kalke (Aghil Formation) in enger Nachbarschaft bilden beispielsweise im CN Karakorum (DICKORÉ 1991) für das Vegetationsmuster kaum auswertbare und offensichtlich auch relativ unbedeutende Faktoren. Stark durchmischte quartäre Lockergesteine (Moränen, glaziofluviale Ablagerungen, Schuttkegel; Löß nördlich der Kunlun Shan-Hauptkette) bedecken als Folge der hohen Reliefenergie, Erosions- und Gletscheraktivität große, in den für Pflanzenwachstum verfügbaren Höhenstufen die des anstehenden Gesteins weit übertreffende Flächen. Die oberflächliche Salz- und Basenanreicherung aufgrund hoher Verdunstung im ariden Karakorum trägt weiterhin zu einer weitgehenden Nivellierung ökologisch wirksamer geologischer Standortsfaktoren bei.

Eine stratigraphisch auffallende Einheit stellen die Formationen des N Karakorum (N Karakoram Terrain) dar, die vom Chapursan Vy. (Batura) bis in die Mustagh Ata-Region und ostwärts entlang der Aghil-Kette und der Karakorum-Verwerfung großflächig anstehen. Sie umfassen mächtige, kaum gestörte karbonische bis jurassische Sedimentfolgen aus Kalk- und Sandsteinen, einschließlich der für den Karakorum namensgebenden schwarzen Schiefer, und bilden aufgrund ihrer leichten Erodierbarkeit die Hauptpässe (Khunjerab P., Aghil P., Karakorum P.).

Je nach den klimatischen Bedingungen bieten die Gesteine unterschiedliche Bedingungen für Pflanzenwuchs. Im extrem ariden N Karakorum bilden Schiefer ungünstige mobile und durchlässige Unterlagen. Die Granite der zentralen Ketten, aber auch Kalksteine, verwittern langsamer und bieten daher mehr hygrisch günstige und stabilere Felsspalten- und Hangfuß-Habitate. BHATTACHARYYA (1989) beschreibt für das etwas feuchtere Rupshu praktisch umgekehrte Verhältnisse. Ophiolithe (basische Eruptiva, Diabase), die im Bereich der Suturen anstehen, und quarzitische Gesteine bilden lokal stabile Bedingungen und Sonderstandorte, sind aber wahrscheinlich in ihrer Standortsqualität ebenso abhängig von der Exposition.

3.3 **Glaziologie und Geomorphologie** - Glaciology and geomorphology

Der Karakorum ist das größte Gletschergebiet außerhalb der Polarzonen, mehr als 15 000 km^2 des Zentral-Karakorum sind permanent von Eis und Schnee bedeckt. Glazialprozesse sind bei weitem die wichtigsten physikalischen Faktoren, die die Geomorphologie des Karakorum determinieren. Die Oberflächenformen umfassen das gesamte periglaziale Inventar von Moränen, glaziofluvialen Terrassen, Talfüllungen, Felsstürzen und Schuttströmen. Sedimente gletschergedämmter Seen wurden bereits von THOMSON (1852) nachgewiesen. Sanddünen treten am Indus von Skardu aufwärts bis in über 5000 m Meereshöhe auf den Sandern der ehemaligen tibetanischen Gletscher auf. Löß kommt am Indus nur sehr lokal und geringmächtig vor, bedeckt aber ein großes aktuelles Akkumulationsgebiet nördlich der Kunlun-Hauptkette

© Biologiezentrum Linz/Austria; download unter www.biologiezentrum.at

(zusammenhängend mit dem Lößgürtel rings um das Tarim-Becken und dem zentralchinesischen Lößgebiet, Gansu) und dringt durch Täler in den NW Karakorum (Mustagh Ata, Taxkorgan) ein.

Die meisten Karakorum-Gletscher enden aktuell zwischen 2800 m (SW Karakorum), 4100 m (CN Karakorum, K2-N Gl.) und höher. Die Zunge des Minapin Gl. (Hunza Vy.) reichte rezent bis 2150 m herab. Das Ausmaß der pleistozänen Vergletscherung Tibets und des Karakorum ist Gegenstand heftigen Disputs (vgl. Zusammenstellung bei HÖVERMANN & LEHMKUHL 1993). Während viele frühere Autoren (z.B. HEDIN 1922, WISSMANN 1959) eine nur unwesentlich höhere eiszeitliche Gletscherbedeckung annehmen, erscheint dem Autor aufgrund geomorphologischer und biogeographischer Indizien der von KUHLE (1991) postulierte, großflächig geschlossene Eisschild über Tibet wahrscheinlicher. Für das letzte Hochglazial wäre demnach für den Karakorum zumindest ein ausgedehntes Eisstromnetz zwischen den Eiskappen über E Pamir und W Tibet und mit großen Auslaß-Gletschern in das Tarim-Becken und den Punjab, anzunehmen.

3.4 **Pedologie** - Pedology

Aufgrund der klimatisch bedingten (s.u.) Hemmung chemischer und biologischer Prozesse überschreitet die Pedogenese in weiten Teilen des Karakorum kaum das Stadium der physikalischen Verwitterung. Die einzige Untersuchung der Böden des CS Karakorum im Rahmen vegetationskundlicher Untersuchungen bietet HARTMANN (1968, 1972). Eigene Untersuchungen im CN Karakorum (DICKORÉ 1991) beschränkten sich aus Zeit- und Gewichtsgründen.

Im CN Karakorum dominieren ausgeprochene Rohböden; Yermosole (Wüstenböden der tieferen Lagen), Lithosole und Gelosole (Hochlagen). Nennenswerte Humushorizonte, von selten über 2-5 cm Mächtigkeit, kommen fast nur in der oberen alpinen Stufe unter Polstern von *Sibbaldia tetrandra* und unter Rasenflecken (z.B. *Carex borii, Stipa concinna*) vor. In Quellsümpfen gebildeter Flachmoortorf (*Carex, Kobresia*) tritt ebenfalls nur sehr lokal, kleinflächig und geringmächtig auf. Ausgedehnte Soda-Ausblühungen als Anzeichen evaporationsbedingter Oberflächenversalzung sind unterhalb 4000-4400 m in allen Expositionen häufig. Die pH-Werte des Oberbodens sind auffallend hoch, pH ($H_2$0) 7,3-8,4 (9,1), mit einer Tendenz in Richtung neutraler Reaktion in der alpinen Stufe über Granit. Die Oberfläche ist meist, außer bei ausgesprochenen Sand- und Geröllrohböden, außerordentlich hart verbacken. Solonchake treten aufgrund des hohen Reliefs und der physikalischen Instabilität ufernaher Grundwasserstandorte nur sehr kleinflächig am Rand von geschützten Quellaustritten auf.

Etwas differenzierter sind die Bedingungen im klimatisch günstigeren CS Karakorum. HARTMANN (1968) stellt die große altitudinale Variation der Böden, die mit verschiedenen Vegetationskomplexen gekoppelt ist, heraus. Die Profile der sand- oder skelettreichen Böden sind einfach. Der Humusgehalt nimmt von < 1% in grauen bis bräunlichen Steppenböden der montan-subalpinen Stauchsteppen (*Kochia - Ephedra intermedia*-Steppe) bis auf >15% in alpinen Rasen- und Gebüschgesellschaften zu. Die pH-Werte nehmen mit der Meereshöhe stark ab. Unterhalb 3900 m Meereshöhe gibt HARTMANN (1968) meist 100% Basensättigung und pH-Werte nur ausnahmsweise unter 8,4 (pH 7,8 - 9,6) an. Aus der alpinen Stufe (*Salix karelinii*-Gebüsch, alpine Rasen) werden braunerdeartige Wiesenböden mit geringerer Basensättigung (um 50%) und entsprechend höherer Ionen-Austauschkapazität bei pH-Werten im neutralen bis schwach sauren Bereich belegt.

Mesotrophe Braunerden und saure Ranker-Braunerden, eventuell auch mit Anhäufung mächtigen Auflagehumus und Podsolidierungserscheinungen, wie sie SCHICKHOFF (1993) aus dem Kaghan Vy. der Himalaya-Südabdachung angibt, sind andeutungsweise im subalpin-alpinen Grenzbereich (ca. 3000-3300 m Meereshöhe) im äußersten SW Karakorum zu erwarten. Entsprechende, im Bereich des Indus-Durchbruchtales kleinflächig vorkommende Pflanzengesellschaften (*Picea smithiana*-Wälder, vereinzelt mit *Abies webbiana*, *Rhododendron anthopogon*-Gebüsch), wurden hier offenbar noch nicht näher untersucht.

4 Klima - Climate

Der Karakorum umfaßt Höhenvarianten der kühlgemäßigten Steppen- und Wüstenklimate am Rand der warmgemäßigten Subtropen (TROLL & PAFFEN 1964). Nach WALTER & BRECKLE (1991) sind W Himalaya und Karakorum als Orobiom des "Dreiecks-Zonoökotons" zwischen dem arid-mediterranen Mittelasien (Irano-Turanisches Vegetationsgebiet), dem arid-gemäßigtem Zentralasien (Zentralasiatisches Vegetationsgebiet) und dem humiden Monsungebiet Indiens (Sino-Himalayisches Vegetationsgebiet) aufzufassen. Die klimatischen Charakteristika der Irano-Turanischen (Winterregen), Zentralasiatischen (ganzjährig arid) und der Sino-Himalayischen Region (Sommerregen) sind fundamental unterschiedlich. Generell kann der überwiegende Teil des Karakorum dem Zentralasiatischen Klima- und Vegetationsgebiet zugerechnet werden (GRUBOV 1963), die komplexe orographische Gliederung bedingt jedoch eine außerordentliche lokale Variabilität des Klima- und Vegetationscharakters (HARTMANN 1972, SCHICKHOFF 1993; Karte 3). WEIERS (1993) bietet einen Überblick zur Klimatologie des W Karakorum.

4.1 Monsungebiet - Monsoon area

Typische ganzjährig humide Monsunklimate besitzen Stationen der äußeren Himalaya S-Abdachung in mittlerer Höhe (800-2500 m) von Nuristan, Swat, Hazara und Kashmir ostwärts (Murree, Balakot, Abottabad, Muzzafarabad, Oghi, Besham Qila, vgl. SCHICKHOFF 1993), mit Niederschlags-Jahressummen von 1000->1500 mm, die zu 30->50 % im Sommer (Juli-September) fallen. Zwischen der Vorkette (etwa N der Linie Dir, Madyan, Naran, Pir Panjal, Kishtwar, Chamba, Kulu) und der Himalaya-Hauptkette herrschen randmonsunale Bedingungen mit Niederschlägen zwischen 600-1200 m und semihumiden Sommern (10-30 % der Niederschläge im Juli-September).

4.2 Winterniederschlagsgebiet - Winter precipitation area

Die Winterniederschläge als Folge westlicher Störungen (FLOHN 1959) wirken sich im Bereich der Depression der Himalaya-Hauptkette zwischen dem Indus-Durchbruch und Zoji P. noch im SW Karakorum aus. Die Stationen Chitral, Drosh, Astor (SCHICKHOFF 1993) und Dras (HARTMANN 1983) erhalten etwa 400-600 mm Jahresniederschlag, zu 40-60 % im Winter und Frühjahr (Februar-April) und mit einer ausgeprägten ariden Periode im Sommer. Vergleichbare Bedingungen herrschen wahrscheinlich nordwestlich des Karakorum auch in mittlerer Höhe der N Abdachung des nordwestlichsten Kunlun (Kongur Shan). Die hier lokal vorkommenden *Picea schrenkiana*-Wälder dürften mit dem Übergreifen feuchterer Luftmassen durch die Alai-Senke und die kashgarische Pforte in Zusammenhang stehen, Klimadaten fehlen jedoch.

Der relative Niederschlagsreichtum im SW Karakorum erklärt sich nach WEIERS (1993) aus der Interaktion von Monsun- und Westzirkulation. Typische Niederschlagswetterlagen im Frühjahr entstehen durch zyklonale Strömungen mediterraner Provenienz, die entlang einer Kaltfront über dem Hindukush von SW in den Karakorum eindringen. Sommerniederschläge sind nach WEIERS (1993) auf westliche und südöstliche Strömungen zurückzuführen, die zwischen den Tiefs über Punjab und Pamir und dem W Tibetanischen Hoch, entlang der Indus-/ Hunza-Durchbruchstäler und östlich des Nanga Parbat-Massivs (Astor, Zoji P.), kanalisiert werden und über den W Karakorum zum Tarim-Becken abfließen.

Die altitudinale Verteilung der Niederschläge weist im randmonsunalen W Himalaya ein doppeltes Maximum auf. Das erste Maximum um 2500 m (mit ca. 1300 mm), ist an monsunale Niederschläge des tropisch-konvektiven Typs gebunden und entfällt im SW Karakorum. Das zweite Maximum um 5500 m (mit > 2000 mm auf der Südabdachung des W Himalaya) ist auf zyklonale Störungen des außertropisch-advektiven Typs zurückzuführen. Die Kurve der altitudinalen Niederschlagsverteilung zeigt im SW Karakorum oberhalb ca. 2500 m einen exponentiellen Anstieg, Wendepunkt bei ca. 4000 m, und bei ca. 5500 m ein etwas kleineres Maximum (ca. 1700 mm) (WEIERS 1993).

© Biologiezentrum Linz/Austria; download unter www.biologiezentrum.at

Floristisch sind das Gebiet der Winterniederschläge und angrenzende randmonsunale Regionen durch das Vorkommen einer Reihe von Irano-Turanischen und Elementen der feucht-gemäßigten Breiten gekennzeichnet. Diese benötigen eine ausreichende Schneedecke und Frühjahrsfeuchtigkeit und verleihen der Vegetation der Höhenstufen im SW Karakorum, am Nanga Parbat und in Kashmir streckenweise ein nahezu mitteleuropäisches Gepräge.

4.3 Arides Gebiet - Arid area

Der größte Teil des Karakorum ist durch ein kalt-gemäßigtes hochkontinentales und ganzjährig arides bis, in den höchsten Lagen, kalt-subhumides Klima gekennzeichnet. Klimastationen fehlen weitgehend, wenige Klimadiagramme liegen aus der Talstufe vor (WALTER & LIETH 1960-1967). Gilgit (SCHICKHOFF 1993), Leh (HARTMANN 1983) und Gar in W Tibet (SONG YONGCHANG 1983) sind durch extrem niedrige Niederschläge von nur 50-200 mm/a ohne ausgeprägtes jahreszeitliches Maximum gekennzeichnet. In den subhumiden höheren Lagen des SW Karakorum und im Bereich der westlichen Hauptkette, ist eine gewisse Annäherung an das Winterregenregime zu erwarten. Der zentralasiatisch-kontinentale Typ weist ebenfalls eine exponentielle altitudinale Zunahme der Niederschläge auf, aber auf einem niedrigerem Niederschlags-Niveau bei größerer Meereshöhe (260-330 mm bei ca. 6000 m).

Das Wüsten- und Halbwüstenklima ist durch extreme diurnale und jahreszeitliche Temperaturschwankungen, in den Monatsmitteln bis über 50 K, gekennzeichnet. Die Jahresdurchschnitts-Temperaturen variieren zwischen > 15 °C in der kollinen Stufe (Gilgit 1490 m: 15,9 °C) und < 0 °C in höheren Stufen (Leh 3514 m: 5,5 °C, Gar 4278 m: 0,2 °C). Die Region der kalten Gebirgswüsten (SONG YONGCHANG 1983) mit Tibetanischem Klima (FLOHN 1959) umfaßt praktisch die gesamte Karakorum-Nordabdachung. Im E Karakorum gehen Wüsten von subalpinem Floren- und Vegetationscharakter praktisch übergangslos in die subnivalen Wüsten W Tibets über. Die montane, subalpine und alpine Stufe des W und S Karakorum umfaßt einen expositionsbedingt mehr oder weniger ausgeprägten subhumiden bis semiariden Gürtel.

Die Höhengrenzen der Vegetationsstufen und die Schneegrenze zeigen einen erheblichen peripher-zentralen Anstieg (WISSMANN 1960, 1961). Im CN Karakorum entspricht die 4400 m-Isohypse als Untergrenze der subhumid alpinen gegen die aride subalpine Stufe und schärfster Floren- und Vegetationsgrenze annähernd der 0 °C-Isotherme der Jahresdurchschnitts-Lufttemperatur (DICKORÉ 1991). Im gesamten Karakorum bestehen erhebliche Expositionsunterschiede, die sich mikroklimatisch hauptsächlich in einer artenreicheren und dichteren Vegetation der strahlungsgeschützten Nordhänge ausdrücken.

Die unterste hygrothermische Zone des SW Karakorum ist nach WEIERS (1993) warm-euarid (Vegetationsperiode > 241 d, Niederschlag 80-200 mm/a) und erstreckt sich vom Indus-Durchbruch, Gilgit Vy., Ishkoman Vy., Hunza Vy. bis zur Durchbruchsschlucht durch die Hauptkette und weniger indusaufwärts bis unterhalb Skardu, Exklave im Shigar Vy. Das Skardu-Becken und der Indus-Oberlauf sind aufgrund ungehindert abfließender tibetanischer Kaltluft und lokaler Windsysteme kühler. Die Verbreitung (trocken-) tropisch-subtropischer floristischer Elemente deckt sich gut mit dem warm-euariden Klimagebiet. Kleinere Exklaven im oberen Hunza-Einzugsgebiet (Batura, lower Shimshal Vy.) wurden von WEIERS (1993) auch aufgrund lokalklimatischer Besonderheiten (geschützte Talkessel, schwarze Gesteine) ausgewiesen. Die warm-semiaride Zone des unteren Indus Vy. (Chilas), charakterisiert durch *Quercus balloot*-Wälder und eine höhere Anzahl Sino-Himalayischer Elemente, erreicht den Karakorum nicht mehr.

Das gemäßigt-semiaride Gebiet (Vegetationsperiode 121-240 d, Niederschlag 351-500 mm/a) entspricht etwa der montanen Vegetationsstufe (potentieller Nadelwald) der größeren Täler des SW Karakorum (Yasin, Ishkoman, Hunza bis Chapursan-Khunjerab-Konfluenz, Indus bis etwa zur Shyok-Einmündung, Shigar, Biafo, ? Exklave: Hushe Vy.).

© Biologiezentrum Linz/Austria; download unter www.biologiezentrum.at

Der übrige SW Karakorum wird als kühl-semiarid (Vegetationsperiode 1-121 d, Niederschlag 351-500 mm/a), bzw. kalt-subhumid (Vegetationsperiode 0 d, Niederschlag 351-500 mm) und kalt-humid (Niederschlag > 800 mm/a) eingestuft. Der trockenadiabatische Temperaturgradient wird von WEIERS (1993) mit -0,82 bis -0,89 K/100 m (Pasu - Khunjerab P.) angegeben.

Geschlossener Permafrost des subnivalen Fließschutt-Gürtels (free gelifluction belt) tritt bei Jahresdurchschnitts-Temperaturen < -3 bis -5 °C oberhalb ca. 4000 m im feuchten SW (Gilgit) und 4700-5000 m im CN und E Karakorum auf.

5 Flora - Flora

5.1 Geschichte der Botanischen Erforschung - History of botanical exploration

Die Erforschungsgeschichte der Karakorum-Flora und die Reiserouten früher Expeditionen wurden von PAMPANINI (1930) und STEWART (1982) ausführlich dargestellt, so daß ich mich auf einige wesentliche Eckpunkte und Ergänzungen beschränken kann.

Die Geschichte der botanischen Exploration des Karakorum beginnt mit *William Moorcroft* (1765-1825), Erstem Veterinärmediziner der East India Company, der im Jahr 1814 von Ladakh nach W Tibet vordrang. Der Grund seiner Reise, der Versuch, eine Herde der Ziegen, die die berühmte Kashmirwolle liefern, zu erwerben, blieb erfolglos, aber er brachte von dieser und einer weiteren Reise im Jahr 1820 zusammen mit *G. Trebeck* (MOORCROFT 1816, MOORCROFT & TREBECK 1841) einige Pflanzen mit, die nach London gesandt wurden. Diese sind die ersten nachweisbaren Belege sowohl aus dem Karakorum, als auch aus Ladakh, W Tibet und Kashmir. *Hugh Falconer*, ein Paläontologe und Nachfolger von *Royle* als Superintendent in Saharanpur, sammelte 1838 in Baltistan, wo er *G. T. Vigne* traf. Mit VIGNE (1842) beginnt die geographische Erforschung von Kashmir, Ladakh und Karakorum.

Wenig später wurde ein erster Höhepunkt der botanischen Entdeckungen im Karakorum und angrenzenden Gebieten mit den Reisen von *T. Thomson*, *R. Strachey* und *J. E. Winterbottom* (1847, 1848) und der *Schlagintweit*-Gebrüder (1855, 1856) erreicht. *T. Thomson*, ein Klassenkamerad von *J. D. Hooker* und Schüler von *W. J. Hooker*, dem ersten Direktor von Kew, war der erste ausgebildete Botaniker im Karakorum. *T. Thomson* brachte von seiner Reise, die von Kunawar über Spiti, Rupshu nach Leh, Skardu, zweimal nach Shyok und Nubra bis zum Karakorum P. (THOMSON 1849), nach Dras und Kashmir führte, überaus reichhaltiges Herbarmaterial mit, das eine Grundlage der "Flora of British India" (HOOKER 1875-1897) bildet. Seine Belege wurden in zahlreichen Duplikaten über die wichtigsten Herbarien seiner Zeit verteilt. Die im "Herb. Ind. Or.", *T. Thomson & J. D. Hooker* ausgegebenen Belege sind jedoch nur recht grob lokalisiert und wurden später offensichtlich nie differenzierter ausgewertet. Der Satz in Kew enthält zusätzlich Etiketten mit dem Sammeldatum, das zusammen mit dem in Tagebuchform geschriebenen, sehr inhaltsreichen und lesenswerten Reisebericht (THOMSON 1852) eine genauere Lokalisierung der Belege erlaubt. Nubra im Sinne *Thomsons* umfaßt übrigens ein weit größeres Gebiet nördlich der Ladakh-Kette als das Tal selbst. Ein Teil der von PAMPANINI (1930) für Nubra zitierten Belege stammt aus dem Shyok Vy. Die Reisen von *Winterbottom* führten nach Gilgit, Astor und Kashmir, die von *Strachey* zusammen mit *Winterbottom* von Kumaon nach W Tibet an die Quellen des Sutlej; die Routen beschreibt STRACHEY (1900).

Die Gebrüder *Schlagintweit*, *Hermann* (1826-1882), *Adolf* (1829-1857) und *Robert* (1833-1885) kamen im Jahr 1854 mit Unterstützung des preußischen Königs als Geographen nach Indien und arbeiteten als Angestellte der East India Company. Sie reisten durch viele Teile Indiens, des Himalaya und Karakorum und erreichten als erste Europäer den Kunlun Shan. *Adolf* drang bis nach Kashgar vor, wo er ermordet wurde. Die *Schlagintweit*-Brüder sammelten außerordentlich reiches Material aller Art. Das sehr gute Herbarmaterial, teilweise aus Gebieten, die später nie wieder untersucht werden konnten, ist über zahlreiche Herbarien verteilt und bislang nur in Bruchstücken ausgewertet worden. Verschiedenste geographische, geologische, klimatische und ethnologische Ergebnisse wurden in umfangreichen Werken (SCHLAGINTWEIT 1861-1866, SCHLAGINTWEIT-SAKÜNLÜNSKI 1869-1880, SCHLAGINTWEIT-

© Biologiezentrum Linz/Austria; download unter www.biologiezentrum.at

SAKÜNLÜNSKI 1876a) dargestellt; die Anlage des Herbariums, mit einer revidierten Übersicht der Fundorte und Meereshöhen, beschreibt SCHLAGINTWEIT-SAKÜNLÜNSKI (1876b).

Im Jahr 1859 bereiste *J. L. Stewart* weite Gebiete Ladakhs und W Tibets. Sein Bericht (J. L. STEWART 1869a) enthält viel botanische Information, korrespondierendes Herbarmaterial (in CAL ?) habe ich nicht gesehen. *G. Henderson*, Teilnehmer der ersten Trade Commission Expedition nach Yarkand unter *T. D. Forsyth*, sammelte auf dem Weg von Ladakh über den Aksai Chin zum Karakash, Kunlun und nach Kashgaria, und veröffentlichte einen detaillierten Bericht (HENDERSON & HUME 1873). Die Belege (in K) sind jedoch oft nur unzureichend beschriftet. Die zweite Trade Commision nach Yarkand und Kashgar wurde von *W. Bellew* und dem Geologen *F. Stoliczka*, der kurz vor der Rückkehr nach Leh 1874 starb, begleitet. Die Belege beider Sammlungen (in K) lassen sich nicht genauer lokalisieren, die von *Bellew* tragen nur die Bezeichnung "Kashgar" oder "Kashmir", wobei offensichtlich in einigen Fällen auch Verwechslungen vorliegen.

C. B. Clarke, einer der fähigsten Botaniker und Kenner schwieriger Gruppen seiner Zeit, sammelte intensiv in Kashmir und erreichte im Jahr 1876 Skardu. Ein kurzer Abstecher führte ihn auch in den Karakorum (ca. 1876-08-01/1876-08-14). Seine Herbaretiketten sind ungenau und enthalten oft nur die Angabe "Karakorum" (in BM, K). Aus Meereshöhen und Sammeldaten läßt sich seine Route, die von Skardu nach Shigar und sehr wahrscheinlich über den Skoro P. (1876-08-07/08) nach Askole am Biafo Gl. (1876-08-10/11) und zurück durch das Braldo Vy. nach Skardu und indusaufwärts nach Dras (1876-08-18) führte, grob rekonstruieren. *Clarke* publizierte keinen speziellen Bericht oder Sammelumstände.

G. M. Giles botanisierte von 1885-1887 in Astor, Gilgit, und als einer der ersten in Chitral und Wakhan. Den "Confidental Report" der Gilgit Mission (LOCKHART, WOODTHORPE & GILES 1889; zitiert nach WENDELBO 1952) konnte ich nicht auffinden; die Rekonstruktion des Itinerars und einiger seiner Lokalitäten bereitet daher Schwierigkeiten. *J. F. Duthie*, ein Systematiker und Agronom, sammelte auf umfangreichen Reisen in Chitral, Hazara, Kashmir, Astor und Gilgit, dort auch im Naltar Vy., einem der floristisch reichhaltigsten Täler des SW Karakorum (DUTHIE 1893, DUTHIE 1894). Dank seines Fachwissens und Interesses an den ökonomisch wichtigen Futterpflanzen, enthalten seine Sammlungen mit die besten Belege der Grasartigen.

ALCOCK (1898), der den Wakhan und Pamir bereiste, bietet keine genauen Fundorte. *W. M. Conway* entdeckte 1892 den "Snow Lake" am Ursprung der Hispar und Biafo Gl. und den dritthöchsten Gipfels des Karakorum (Hidden Peak, 8035 m); *Calciati* kartierte im Saltoro-Gebiet. Beide Arbeiten, CONWAY (1894) und CALCIATI (1914) bieten auch floristische Angaben aus dem Zentral-Karakorum. MEEBOLD (1909) berichtet über eine botanische Reise von Kashmir nach Ladakh; sein Herbar wurde jedoch ebenfalls nicht zusammenhängend ausgewertet. Die Ära *R.. R. Stewart* beginnt mit der "Flora of Ladak" (STEWART 1916-1917). Das von *J. Visser-Hooft* auf mehreren Expeditionen (vgl. VISSER & VISSER-HOOFT 1935-1940) gesammelte Material wurde von HENRARD (1923) und DOLK (1929) ausgewertet. MASON (1928) untersuchte das Shaksgam Vy. im NE Karakorum und sammelte ebenfalls einige Pflanzen. BOSSHARD (1932: Gefäßpflanzen bearbeitet von SCHMID in BOSSHARD) veröffentlichte eine Liste der während der Expedition 1927-1928 in Ladakh, E Karakorum, Kunlun und Kashgaria gesammelten Pflanzen (vgl. TRINKLER 1932, DE TERRA 1932). Nach den Vorarbeiten von PAMPANINI (1915, 1916a, 1916b, 1926a, 1926b, 1929), endete schließlich mit der umfassenden Darstellung des Wissensstandes (PAMPANINI 1930, 1934) die erste Erforschungsphase der Karakorum-Flora.

Pioniere der Erforschung W und C. Tibets, die in wechselndem Umfang Pflanzen sammelten und zur floristischen Kenntnis beitrugen, waren nach *Falconer: Thorold* (BOWER 1893, 1894), GRENARD & DUTREUIL DE RHINS (1897-1898, botanische Bearbeitung: FRANCHET 1895, 1897, FRANCHET in GRENARD 1898), STRACHEY (1900) und DEASY (1901, botanische Bearbeitung: BAKER in DEASY 1901). Zusammenfassend wurde das Material von HEMSLEY (1894, 1902) bearbeitet. FRANCHET (1896) beschreibt auch eine Sammlung von *M. E. de Poncins* aus dem E Pamir. Der Nordosten Tibets wurde von *N. M. Przewalsky* bereist, auf dessen reicher Sammlungsgrundlage MAXIMOWICZ (1889a, 1889b) eindrucksvolle, leider unvollendet gebliebene botanische Werke publizierte. DANGUY (1908) bearbeitete eine Sammlung von *Lacoste*; OSTENFELD & PAULSEN in HEDIN (1922) das von *S. Hedin* gesammelte

© Biologiezentrum Linz/Austria; download unter www.biologiezentrum.at

Material (HEDIN 1922, etc.). *H. Handel-Mazzetti*, der umfangreich in SE Tibet tätig war, bearbeitete auch eine kleine Sammlung von *E. Zugmayer* aus NW / C. Tibet (HANDEL-MAZZETTI 1930). SKRINE (1925) gibt eine erste Schilderung des Kongur Shan, der mit *Picea schrenkiana*-Wäldern an die Vegetationsverhältnisse des Tian Shan erinnert.

5.2 Neuere floristische Arbeiten - Recent floristics

Abgesehen von einer Pflanzenliste aus Kashgaria, Kunlun und Kashmir (PERSSON 1938), Untersuchungen im Hindukush und Chitral von HAECKEL & TROLL (1938) und der klassischen Vegetationskarte des Nanga-Parbat-Massivs von TROLL (1939), brachte die erste Hälfte des 20. Jahrhunderts weiterhin keine nennenswerten Fortschritte in der botanischen Erforschung des Karakorum und angrenzender Gebiete.

Eine erneute Aktivitätsphase setzte mit kleineren Artenlisten als Ergänzung zu PAMPANINI (1930, 1934) ein: GILLI (1957, 1962) über das Material österreichischer und WILLIAMS (1965) über Funde italienischer Expeditionen. WEBSTER & NASIR (1965) geben eine gute Übersicht über Flora und Vegetation des Hushe Vy. im CS Karakorum. KITAMURA (1960) faßt botanische Ergebnisse japanischer Expeditionen nach Afghanistan zusammen, die von KITAMURA (1964) auf Swat, Hazara und den S Karakorum ausgeweitet werden. HARTMANN (1966, Korrekturen HARTMANN 1984) führte die wohl sorgfältigste floristische Arbeit im Biafo-Gebiet des CS Karakorum durch, die durch eine ausführliche Darstellung der Vegetation (HARTMANN 1968, 1972) ergänzt wurde.

In der Folge wurde vorwiegend der relativ leicht zugängliche SW Karakorum Ziel zahlreicher wissenschaftlicher oder Bergsteiger-Expeditionen. Bemerkenswert ist vor allem die Sammeltätigkeit von *R.. R. Stewart*, die zu umfangreichen Checklisten für verschiedene angrenzende Gebiete, einzelne systematische Gruppen und die gesamte Flora Pakistans (STEWART 1972), sowie zur Übersicht über die Erforschungsgeschichte (STEWART 1982, hier auch Angaben über weitere Sammler), führte. Weitere wichtige, in der vorliegenden Übersicht ausgewertete Sammlungen sind die von *R.. Scott Russell* (Hispar, Shigar, Biafo; BM), *S. Bowes Lyon* (Chitral, Ghizar, Yasin, Ishkoman; BM, K) *J. D. A. Stainton* (Chitral, Ghizar; BM, W) und *O. Polunin* (Gilgit, Hunza, Hispar, Kashmir; BM). Spezielle floristische Arbeiten beschränkten sich, abgesehen von DICKORÉ (1991): CN & N Karakorum (Yarkand, Shaksgam, K2-North), W Kunlun und Kashgaria, auf Nachbargebiete.

5.3 Floren, Bearbeitungen angrenzender Gebiete - Floras, contributions to adjacent areas

„Flora of British India" (HOOKER 1875-1897) ist bis heute eine primäre Referenz für taxonomische Botanik des Indischen Subkontinents, einschließlich des Himalaya. „Flora of Pakistan" (NASIR & ALI 1970-), basierend auf der Checkliste von STEWART (1972), deckt die Karakorum-Südabdachung ab; die Bearbeitung des schwer zugänglichen zentralasiatischen Grenzgebietes in Karakorum und Kashmir ist jedoch teilweise unzureichend. „Plantae Asia Centralis" (GRUBOV 1963-) gibt zuverlässige Daten für die chinesische Karakorum-/Kunlun-Nordabdachung, das für dieses Werk verfügbare Material (in LE) dünnt aber offensichtlich gegen die Karakorum-Hauptkette und Tibet stark aus. Chinesische Floren mit Bezug zur Flora des Karakorum sind „Flora Xizangica" (WU CHENG-YIH 1980-1986) und FLORA IN DESERTIS SINICORUM, diese sind jedoch im extremen W bzw. SW ebenfalls großteils inkonsistent. Das Pamir-Plateau decken FEDTSCHENKO (1903-1915) sowie „Flora Tadzhikskoy SSR" (OVCZINNIKOV 1957-) ab. Das Gebiet der „Flora Iranica" (RECHINGER 1963-) schließt Randgebiete des südwestlichsten Karakorum ein, die Zentralasiatischen und Sino-Himalayischen Elemente sind jedoch häufig unzureichend bearbeitet.

Floristische Information vorwiegend aus angrenzenden Gebieten geben für Wakhan: PODLECH & ANDERS (1977), HUSS (1978); Chitral: WENDELBO (1952), CHAUDRI (1952, „medical plants"), CHAUDRI 1957; Astor: KAZMI & SIDDIQUI (1953, „medical plants"); Deosai: STEWART (1961); Zanskar: SEYBOLD & KULL (1985); Swat: STEWART (1967a); Kashmir RAO (1961), RAO (1967),

© Biologiezentrum Linz/Austria; download unter www.biologiezentrum.at

DHAR & KACHROO (1983, Grasartige fehlen). SHARMA & JAMWAL (1988) beginnen eine Inventur des floristisch reichhaltigen Liddar Vy. in Kashmir; ASWAL & MEHROTRA (1993) geben einen soliden Überblick der Flora von Lahul (Lahaul) und Spiti, der kontinentalsten inneren Himalaya-Täler Indiens (Himachal Pr.). Arbeiten über Ladakh schließen Teile des SE Karakorum (Leh) ein: KACHROO, SAPRU & DHAR (1977), HARTMANN (1984) und BILLIET & LÉONARD (1986).

Afghanistan wird von AITCHISON (1888), KÖIE & RECHINGER (1954-1965), KITAMURA (1960), GREY-WILSON (1974), BRECKLE (1974) abgedeckt, speziell das floristisch interessante Kurram Vy. / Safed Koh, im Grenzbereich der Irano-Turanischen und Sino-Himalayischen Florenregion behandeln AITCHISON (1881-1882) und STEWART (1967b). Benachbarte Teile von Indien und Pakistan untersuchen STEWART (1869b: Punjab), BRANDIS (1874: "Forest flora"), STEWART (1957-1961: Rawalpindi District), BEG & KHAN 1974, BEG & SAMAD 1974 (Malakand Division), ALI (1978: Pakistan) sowie BRIJ MOHAN SHARMA & KACHROO (1981: Jammu). Interessant für floristische Fragestellungen im Karakorum sind auch Arbeiten aus weiter entfernten Gebieten, wie Mongolei (NORLINDH 1949), Tian Shan (OSTEN-SACKEN & RUPRECHT 1869, MERZBACHER 1912), Pamir, Himalaya (Everest-Region: MIEHE 1987, HUANG RONGFU 1988) und S Tibet (HUANG RONGFU & MIEHE 1988).

In weiterem Maßstab für die Identifikation und Kennzeichnung der Karakorum-Flora von Interesse sind die folgenden Standardfloren: FLORA REIPUBLICAE POPULARIS SINICAE, ICONOGRAPHIA CORMOPHYTORUM SINICORUM, „Flora USSR" (KOMAROV 1934-1964), „An Enumeration of Flowering Plants of Nepal" (HARA, WILLIAMS & al. 1979-1982), „Flora of Bhutan" (GRIERSON & LONG 1983-). „Flora Europaea" (TUTIN & al. 1964-1980), „Illustrierte Flora von Mitteleuropa" (HEGI, ed. 1: 1906-1931, ed. 2: 1936-, ed. 3: 1966-) und „Süßwasserflora von Mitteleuropa" (CASPER & KRAUSCH 1980) sind weitere Quellen für Informationen über weitverbreitete Eurasiatische Sippen. Historische Arbeiten mit Florencharakter (WALLICH 1830-1832, ROYLE 1839-1840, CAMBESSEDES & DECAISNE in JACQUEMONT 1844, KLOTZSCH & GARCKE 1862, MAXIMOWICZ 1889a, 1889b) sind als primäre Referenz in vielen Fällen unerläßlich. Populäre Pflanzenführer, mit angesichts der komplexen Himalayisch-Tibetischen Flora wichtiger Funktion als Bestimmungshilfen, sind z.B., „Beautiful flowers of Kashmir" (BLATTER 1928-1929), „Flowers of the Himalaya" (POLUNIN & STAINTON 1984, STAINTON 1988) und „Alpine plants of China" (ZHANG JINGWEI 1982).

5.4 Die Flora des Karakorum / Anlage der Flora, Korrekturen, Anmerkungen - The Flora of the Karakorum / Plan of the Flora, corrections, notes

Die vorliegende Flora enthält alle Arten und Unterarten der Monocotyledoneae, die dem Autor aus dem Karakorum als einheimisch, eingeführt oder in größerem Maßstab kultiviert bekannt wurden. Kursorisch werden nah verwandte, verwechslungsträchtige, in Nachbargebieten häufige oder für den Karakorum zu erwartende Taxa berücksichtigt.

Für die vorliegende Arbeit wurde Material folgender Herbarien eingesehen: B, BM, GAT, GOET, GZU, H, K, KYO, M, W, WHB, Z (unterstrichen: repräsentative bzw. angestrebt vollständige Auswertung der Bestände von Monocotyledoneae des Karakorum). Neben diesem Herbarmaterial und der zitierten Literatur bilden die folgenden Sammlungen eine weitere Grundlage der vorliegenden Bearbeitung (geschätzte Gesamtanzahl der Belege):

A.Bosshard, F.Klötzli & A.Schaffner 1989 (zitiert *Klötzli & al.*): Gilgit, Hunza, Batura, Khunjerab, Chilas (ca. 2000 Belege, Z, Dubletten GOET).
G.Braun 1990, 1991: Hunza (ca. 600 Belege, derzeit in GOET).
B.Dickoré 1986: Yarkand, Shaksgam, K2-North, W Kashg., W Kunlun (ca. 1000 Belege, GOET).
F.Gartner 1975: Ishkoman, Gilgit, Hunza, Hazara (ca. 1000 Belege überwiegend aus der Talstufe; GZU).

© Biologiezentrum Linz/Austria; download unter www.biologiezentrum.at

G. & S.Miehe 1990: Yasin, Gilgit, Batura, Khunjerab, Skardu, Saltoro, Deosai, Hazara; 1991: Yasin, Ishkoman, Hunza, Skardu, Shigar, Shimshal, Batura, Khunjerab, Mintake, Taxkorgan, Mustagh Ata, W Kashgaria, Kongur, Chitral; 1992: Yarkand, Karakash, Aksai Chin, W Kashg., Kongur, W Kunlun, Changtang, W Tibet. 1993: W Tibet (Manasarowar Lakes, Burang Vy., Upper Indus). (ca. 10000 Belege einschließlich Kryptogamen, vegetationskundliche Fragestellung, Sonderstandorte unterrepräsentiert; derzeit in GOET, Teile in B, H (*Cyperaceae*), ISL, K, etc.).
R. Hansen 1992: Astor (ca. 200 Belege, GOET).
W.Holzner & M.Kriechbaum 1992, 1993: Leh, Zanskar, Rupshu, Himachal Pr. (ca. 1000 Belege, WHB, Dubletten GOET, W).
M.Nüsser 1993, 1994: Chilas, Astor (Nanga Parbat, ca. 1700 Belege, B).
J.Poelt 1991: Skardu, Shigar, Deosai (ca. 300 Belege, Phanerogamen-Sammlung mit *Miehe*; GZU).
U.Schickhoff 1990: Hazara (Kaghan Vy.; GOET, H (*Cyperaceae*), K etc.; Numerierung 1992 neu beginnend, zitiert als *Schickhoff 90/..*); 1992: Gilgit, Hunza, Skardu; 1993: Gilgit, Hunza, Skardu, Shigar, Biafo, Chilas, Astor, Deosai, Hazara. (ca. 2000 Belege vorwiegend aus der Waldstufe; derzeit in GOET).

Da die endgültige Aufbewahrung der aktuell bearbeiteten neuen Sammlungen in vielen Fällen noch nicht feststeht, werden Herbarium-Referenzen nur ausnahmsweise zitiert. Vorgesehen und z.T. bisher erfolgt ist die Verteilung von Dubletten an die Herbarien B, GOET, K, ISL, LI, PE und W. Belege der wichtigen Sammlungen von *H.Hartmann* (Skardu, Shigar, Biafo, Leh, Zanskar, Rupshu) und *D.Podlech* (Afghanistan, einschließlich Wakhan: *O.Anders*) finden sich, soweit ohne Herbariumangabe zitiert, in den jeweiligen Privatherbarien.

Eine frühere Arbeit (DICKORÉ 1991) enthält im Bereich der Monocotyledoneae, wie viele andere Bearbeitungen auch, überproportional viele Irrtümer und Unsicherheiten, die hier korrigiert werden sollen:

(DICKORÉ 1991):	hier:
Allium cf. humile	*Allium* cf. *oreoprasum*
Allium sp.	*Allium* cf. *oreoprasum*
Blysmus sinocompressus	*Blysmus compressus*
Carex atrofusca ssp. minor	*Carex atrofusca*
Carex haematostoma var. submacrogyna	*Carex alexeenkoana* X *C. borii* ?
Carex melanantha	*Carex moorcroftii*
Carex montis-everestii	*Carex borii*
Carex cf. pycnostachya	*Carex curaica*
Eleocharis quinqueflora	*Eleocharis quinqueflora* und *Trichophorum pumilum*
Kobresia deasyi	*Kobresia schoenoides*
Kobresia stenocarpa	*Kobresia royleana*
Calamagrostis holciformis	*Calamagrostis tianschanica*
Elymus cf. dentatus	*Elymus dentatus*
Elymus schrenkianus	*Elymus schrenkianus* (überwiegend) und *E. schugnanicus* (Aghil)
Festuca tibetica	*Festuca tibetica* (überwiegend) und *F. coelestis* (Kunlun)
Poa litvinoviana	*Poa lipskyi*
Poa poophagorum	*Poa attenuata*
Puccinellia kashmiriana	*Puccinellia tenuiflora*
Puccinellia tenuiflora	*Puccinellia tenuiflora* (überwiegend) und *P. himalaica* (Aghil)
Juncus ambiguus	*Juncus bufonius* s.l.
Potamogeton pectinatus	*Potamogeton amblyphyllus.*

Im Einzelfall unterschiedliche Bestimmungen anderer Autoren werden im Folgenden nach Möglichkeit diskutiert und, soweit auf systematisch abweichender Deutung beruhend, mit der Formel "auct. non ..." unter der hier akzeptierten Sippenfassung aufgeführt.

Das umfangreiche, in jüngerer Zeit in den nationalen Herbarien von Pakistan, Indien, China und Nachbarländern angesammelte Material, aber auch Belege anderer wichtiger Herbarien, konnte für die vorliegende Untersuchung nicht genutzt werden. In *Fl.Pak.* (Herbarien ISL, KUH, RAW) und *Pl.As.Centr.* (vorwiegend Herbarium LE) zitierte Belege und weitere Literaturangaben wurden, soweit sie verläßlich erschienen oder zugeordnet werden konnten, übernommen. Zitierte Belege ohne Sichtvermerk und Quellennachweis entstammen *Fl.Pak.*, die den größten Teil des Floreninventars des Karakorum einschließt.

Obwohl Teile der Karakorum-Flora wahrscheinlich weit besser belegt sind als für diese Arbeit ausgewertet werden konnte, sind weitere Feldarbeiten und Aufsammlungen für ein besseres Verständnis der Verbreitungs- und Differenzierungsmuster sicher förderlich. Die Repräsentanz von Belegen ist in den europäischen Herbarien, aber sicher auch in den Herbarien der Anrainerstaaten, nach wie vor geographisch sehr uneinheitlich und reflektiert oft die verschiedenen Schwierigkeiten, bestimmte Gebiete zu erreichen. Allerdings korrespondiert die Erreichbarkeit zu einem gewissen Maß auch mit der floristischen Diversität. Gilgit und Hunza z.B. sind heute über den Karakorum Highway relativ einfach zugänglich und vergleichsweise gut bekannt. Aufgrund ihrer extrem abwechslungsreichen natürlichen Ausstattung bei relativ hoher Humidität, beherbergen diese Gebiete aber wahrscheinlich auch die größte Artenzahl. Nur sehr wenig und lückenhaftes Material ist aus dem Norden und Osten des Karakorum, sowohl aus dem chinesischen als auch dem indischen Teil, verfügbar. Dieses beruht zum einen auf der schweren Zugänglichkeit aus politischen Gründen. Zum anderen schränken extremes Relief, Trockenheit und die außerordentlich geringe Vegetationsdichte, korreliert mit niedriger Artenzahl, sowohl die Möglichkeiten des notwendigen Transportes mit Tragtieren als auch die Attraktivität für Botaniker ein. Einige Gebiete mit sicher extrem artenarmer Flora, z.B. Upper Yarkand, wurden anscheinend seit den SCHLAGINTWEITs nicht mehr untersucht. Die Anzahl der aus den einzelnen Gebieten des Karakorum bekannten Monocotyledoneae gibt Fig. 11 an.

In Bezug auf die Habitate ist die hochalpine Flora nach wie vor in den Sammlungen unterrepräsentiert, ebenso Arten der jedenfalls wenigen, kleinen und sehr lokalen Kultur- und Wasserzuschußflächen wie Flußoasen und Quelltälchen. Eine besondere Herausforderung dürfte die floristische Untersuchung der relativ wenigen größeren Felswände in mittleren Höhenlagen bedeuten. Diese Standorte könnten, vorzugsweise in Nordexposition, Arten beherbergen, die der Beweidung, Klimaschwankungen und anderen Umweltkatastrophen entgangen sind.

Die Vegetationszeit des Karakorum ist sehr kurz und in der alpinen Stufe im wesentlichen auf die Monate Juli und August kontrahiert. In den Tälern können zu dieser Zeit jedoch einige frühblühende Arten (Therophyten und Geophyten überwiegend Irano-Turanischer Herkunft) übersehen werden, während sich andere (hauptsächlich Vertreter der Sino-Himalayischen und Zentralasiatischen Florengebiete) erst sehr spät entwickeln. Die jedenfalls sehr limitierte Frühjahrsflora des Karakorum verdient weitere Aufmerksamkeit ortsansässiger oder überwinternder Botaniker, da die meisten Pässe bis in den frühen Sommer blockiert sind.

Eine weitere Strukturierung und Präzisierung der chorologischen (**D**:) und ökologischen (**E**:) Angaben in der folgenden Übersicht wäre sicher wünschenswert, erforderte aber umfangreiche weitere Arbeiten und Definitionen. Die ökologische Charakterisierung, einschließlich des angegebenen altitudinalen Vorkommensbereichs und der Zuordnung zu Höhenstufen, beschreibt, soweit nicht anders angegeben, ausschließlich die Situation im Karakorum. Die chorologische Einordnung hängt in hohem Maß von der taxonomischen Abgrenzung, die klimatologische (Höhenstufen-) Klassifikation der einzelnen Sippen darüber hinaus von lokalen Begebenheiten ab. Die diesbezüglich folgenden Angaben sind generell nur als ein erster Ansatz zu betrachten, der im Einzelfall anhand relativ weniger zusätzlicher Daten, eventuell grundsätzlich zu revidieren wäre.

Bestimmungsschlüssel, teilweise von provisorischem Charakter, werden für einen Teil der Gattungen angeführt, soweit das vorliegende Material eine kritische und mehr oder weniger von früheren Bearbeitungen abweichende Aufschlüsselung zuläßt. Synoptische Übersichten größerer Gattungen sind rein informeller Natur und beinhalten keinen für eine kritische Revision der jeweiligen Gattungen ausreichenden taxonomischen Ansatz.

D: SW Karakorum, W Himalaya (Kashmir - Nepal, Bhutan). *W Himal.*

E: 2630-3610 m, mont., not common in the SW. Coniferous forests (*Picea smithiana*, *Pinus wallichiana*, *Juniperus excelsa*) and scrub (*Juniperus sibirica*), apparently of a somewhat wider ecological amplitude than *Polygonatum geminiflorum*, but often vegetative.

N: The plants from the Karakorum have narrow leaves with uncinate tip, long peduncles and glabrous filaments; the stems, lower leaf surfaces and even peduncles are rather densely puberulent, the perianth is clearly pink at the tip. Indument and leaf shape are, however, very variable, and many specimens are only vegetative. They seem to be distinct from *P. verticillatum*, but other taxa of the poorly understood complex may be involved. Some characters (long hairs) may indicate introgression from *P. geminiflorum*. **Polygonatum sewerzowii** REGEL 1868 (*Polygonatum aflatunense* B. FEDTSCH. 1915, *Polygonatum haussknechtii* BORNM. & SINT. 1903) - **Ic.:** Fl.Iran.165: pl.171. **D**: NE Iran - Turkmenia, N Afgh., W Pamir - Tian Shan, is apparently also closely related. Uncinate leaf apices are furthermore characteristic of **Polygonatum cirrhifolium** (WALL.) ROYLE 1839, a species of the C. and E Himalaya. The group deserves further studies.

D: Temp. Eurasia, N Africa. *Euras.*

E: (2600) 2700-4130 (4330) m, subalp., not common (but locally dominant). Moist sands of river-banks (*Kobresia royleana, Carex pseudofoetida, Equisetum ramosissimum*); wet or shallowly flooded places by springs, in fens (*Eleocharis quinqueflora, Carex orbicularis*) and in *Kobresia schoenoides*-moors.

N: *B. compressus* is quite variable in C.Asia and usually more robust than in Europe. Possibly, this is a result of introgression from *B. rufus*. The taxon of the Karakorum and Tibet (Pamir to Kansu and Sichuan) may be placed under var. *brevifolia* (*B. sinocompressus* TANG & WANG), which possibly

© Biologiezentrum Linz/Austria; download unter www.biologiezentrum.at

includes var. *sikkimensis* (Sikkim) and var. *dissita* (Turkestan, Kumaon) sensu CLARKE (1898) as well.

? 23. Blysmus rufus (HUDSON) LINK, Hort. Berol. 1: 278. 1827

E Wuma (N 32°34' E 83°22') 4650-4660 m, *Miehe+9680a!*. Changtang: Lungmo Co 5150 m, *Miehe 8192!*.

D: Eurasia S to Pamir, Kunlun, W & S Tibet; N America. *Holarct.*

E: ? c. 3350 m, subalp., rare. (Generally:) Flushes, lake shores, superficially dry gravel beds, sand plains. Apparently more tolerant of (or requiring) a higher salt content than *B. compressus*. A markedly alpine species in adjacent W Tibet (4700-5100 m).

N: *B. rufus* occurs in E Pamir, Kunlun, and W & S Tibet. It may well be expected in adjacent areas of the Karakorum, but is not yet found there with certainty. The Tibetan populations of *B. rufus* are very variable; but usually the species is easily distinguished from *B. compressus*. *Leptolepis tibetica* BOECK., from (part of ?) the type material (*Schlagintweit 6467*) may be referable to *B. rufus*. The material, however, has flowers/fruits almost destroyed and probably contains different elements as well. It is found under *"Carex microglochin"* in K!, under *"Blysmus compressus"* (*C.B.Clarke* in sched. K!) in B (perhaps destroyed) and BM!. On the BM! material no perigon setae could be found and the leaves are so tightly inrolled and almost smooth at the tip, that *B. rufus* is more probable. Young or reduced plants of *Carex microglochin* and *Blysmus rufus* sometimes resemble each other.

D: Eurasia, Africa. *Euras.*

E: 2500 m, coll., rare in the SW. Shore of small saline lake. (Generally:) Wet ± saline habitats.

N: Since the taxonomy of the genus is rather difficult, the above name is meant in an aggregate sense. The single specimen seen from the Karakorum consists of small plants with congested inflorescences and light brown glumes. It may be referable to *Bolboschoenus affinis* ROTH. Pl.As.Centr. reports from Kashgaria: *Bolboschoenus maritimus, Bolboschoenus planiculmis* (Fr. SCHMIDT) EGOROVA 1967 - **Ic.:** Fl.Desert.Sin.1: fig.49(7-11), and *Bolboschoenus popovii* EGOROVA 1967 (*Scirpus affinis* auct. non ROTH: OSTENF. in HEDIN 1922, *Scirpus maritimus* auct. non L., *Scirpus strobilinus* auct. non ROXB.) - **Ic.:** Fl.Desert.Sin.1: fig.49(12-16).

* **Bulbostylis barbata** (ROTTB.) C. B. CLARKE in HOOKER f. 1893 (*Scirpus barbatus* ROTTB. 1772) - **A**: Reported from Swat, Hazara, Kashmir (Ann.Cat.Pak.). **D**: Old World trop. and subtrop.

© Biologiezentrum Linz/Austria; download unter www.biologiezentrum.at

* **Bulbostylis densa** (WALL.) HANDEL-MAZZ. in KARSTEN & SCHENCK 1930 (*Scirpus densus* WALL. in ROXB. 1820) - **Ic.:** Fl.Xizang.5: fig.197. **A**: Reported from Kashmir (Ann.Cat.Pak.). **D**: Africa, S & E Asia.

Carex:

This is one of the largest genera of flowering plants of the Karakorum, probably before *Saussurea*. Species of *Carex*, however, occupy a significant position only in the vegetation of the humid parts of the SW Karakorum, otherwise many species are confined to local water-surplus habitats. Species of *Kobresia* are generally more representative of the alpine vegetation. The taxonomy of *Carex* in the Karakorum is rather confused, although the species delimitation, with some exceptions, presents few problems. These, however, are evident in the sections *Foetidae*, *Aulocystis* and *Atratae*, which have centres of diversification in the Karakorum and adjacent mountains. There is also some evidence of hybridisation in these groups.

Synopsis of *Carex* (Fl.Eur., Pl.As.Centr., KÜKENTHAL, Fl.Turkey):

Subgenus *Indocarex* (BAILLON) KÜK.

Sect. *Indicae* KÜKENTHAL: (*C. filicina*), (*C. sanguinea*)

Sect. *Japonicae* ?: (*C. ivanovae*)

Subgenus *Vignea* (BEAUV.) KÜKENTHAL

Sect. *Heleoglochin* DUMORT.: (*C. diandra*)

Sect. *Vulpinae* (J. CAREY) CHRIST: *C. vulpinaris*

Sect. *Phaestoglochin* DUMORT.: (*C. foliosa*)

Sect. *Divisae* CHRIST ex KÜKENTHAL: (*C. divisa*)

Sect. *Physodae* CHRIST ex KÜKENTHAL: *C. stenophylla*

Sect. *Foetidae* (L. H. BAILEY) KÜKENTHAL: *C. curaica, C. pseudofoetida, C. sagaensis*

Sect. *Multiflorae* KUNTH: (*C. nubigena*)

Sect. *Remotae* (ASCHERSON) C. B. CLARKE: (*C. remota*)

Sect. *Canescentes* (FRIES) CHRIST: (*C. canescens*)

Subgenus *Phyllophora* (DEGLAND) PETERM. (Subgenus *Primocarex* (KÜK. (KÜK.) p.p.)

Sect. *Leucoglochin* DUMORT.: *C. microglochin, C. parva*

Subgenus Carex

Sect. *Carex* (sect. *Paludosae* (FRIES) CHRIST, sect. *Pseudocypereae* (L. H. BAILEY) KÜKENTHAL, sect. *Vesicariae* (O. F. LANG) CHRIST): (*C. acutiformis*), (*C. pseudocyperus*), *C. pamirensis, C. songarica*

Sect. *Hymenochlaenae* DREJER: (*C. brunnea*), (*C. longicruris*)

Sect. *Capillares* (ASCHERSON & GRAEBNER) NELMES: *C. karoi*

Sect. *Fulvellae* (ANDERS.) FRIES ex CHRIST (sect. *Spirostachyae* (DREJER) L. H. BAILEY): *C. diluta*

Sect. *Ceratocystis* DUMORT. (sect. *Flavae* (O. F. LANG) CHRIST): *C. viridula*

Sect. *Hirtae* TUCKERM.: (*C. ligulata*)

Sect. *Digitatae* (FRIES) CHRIST: (*C. cardiolepis*), (*C. laeta*)

Sect. *Trachychlaenae* DREJER: (*C. inanis*), (*C. schlagintweitiana*), (*C. setigera*)

Sect. *Lamprochlaeneae* (DREJER) L. H. BAILEY: (*C. supina*), (*C. tangulashanensis*), (*C. turkestanica*)

Sect. *Aulocystis* DUMORT. (Sect. *Frigidae* CHRIST): (*C. alajica*), *C. alexeenkoana, C. atrofusca, C. borii*, (*C. chitralensis*), (*C. haematostoma*), (*C. kashmirensis*), (*C. montis-everestii*), *C. nivalis, C. oligocarya, C. plectobasis*, (*C. psychrophila*), *C. setosa, C. stenocarpa*

Sect. *Atratae* CHRIST: (*C. cruenta*), *C. decaulescens*, (*C. duthiei*), (*C. gracilenta*), *C. infuscata*, (*C. lehmannii*), *C. melanantha, C. moorcroftii*, (*C. obscura*)

Sect. *Phacocystis* DUMORT. (Sect. *Acutae* (FRIES) CHRIST): (*C. cernua*), *C. orbicularis*

Key to *Carex* of the Karakorum (including some of the related species):

1. Inflorescence a narrow, usually few-flowered spike, leaves setaceous. Racheola present, included into or protruding from the utricle **2**
+ Inflorescence usually compound of several spikes, sometimes very congested, if (apparently) a single spike, then this ± oval. Leaves usually broader, plicate. Racheola usually absent **3**
2. Rhacheola protruding from the 3-5 mm long utricle ..... **C. microglochin**
+ Rhacheola included into the 5-7 mm long utricle ..... **C. parva**
3. Spikes all alike, hermaphrodite, stigmas 2 (*Vignea*) **4**
+ Spikes dissimilar, upper spike(s) usually male, lower female, sometimes mixed in between. Stigmas usually 3, sometimes 2 ..... **8**
4. Laxly caespitose, with short rhizomes. Utricles with strong nerves ..... **C. vulpinaris**
(Utricles with indistinct nerves: **C. diandra**)
+ Not caespitose, with long creeping rhizomes **5**
5. Utricles with prominent veins. Inflorescence oblong-ovoid, usually not lobed. Female glumes acute. Glumes and utricles usually reddish-brown. Rhizomes thin ..... **C. stenophylla**
(Inflorescence distinctly lobed, the separate spikes clearly evident at least at the base. Female glumes cuspidate or aristate. Rhizomes thick: **C. divisa**)
+ Utricles with faint veins. Glumes and utricles usually dull to greenish brown **6**
6. Tall plants, 20-40 cm high. Leaves flat ..... **C. curaica**
+ Usually smaller plants, 5-15 cm high. Leaves flat or folded **7**
7. Plants with long creeping rhizomes, usually not forming dense cushions. Leaves flat or folded, ± straight, gradually narrowed into a short trigonous or flat tip. Stems straight, usually exceeding the leaves, smooth or scabrid, usually sharply triangular. Nut broadly oval to suborbicular in outline ..... **C. pseudofoetida**
(**C. enervis** is very similar to this and to *C. stenophylla*, but has reddish-brown utricles without visible nerves)
+ Plants with short rhizomes, forming dense cushions. Leaves narrowly convolute to oblique-trigonous, with a flat, obtuse tip, usually strongly curved. Stem usually smooth, ± rounded in cross-section, often shorter than the leaves and curved downwards. Nut oval in outline ..... **C. sagaensis**
8. Stigmas 2. Utricles biconvex, broadly ovate, glabrous, without a beak ..... **C. orbicularis**
+ Stigmas 3. Utricles trigonous, biconvex or much flattened, with or without a beak, often hairy or spiny at least at apex **9**
9. Inflorescence reduced to (apparently) one (to three) compact spike(s). Utricles glabrous, small, 2.5-3 mm, attenuate at apex. Low growing high alpine plants with short ascending stolons. Nut with convex faces ..... **C. borii**
(± rhizomatous or with longer stolons. Nut with concave lateral faces: **C. montis-everestii** depauperate forms)
+ Inflorescence compound of several, usually well separated spikes. Utricles glabrous, hairy or spiny, with or without beak **10**
10. Utricles hairy on at least part of the surface of the body **11**
+ Utricles glabrous on the surface of body, though often ciliate or hispid-denticulate on margin or on beak **23**
11. Female spikes long, narrowly cylindric, ± erect **12**
+ Female spikes short, broader, erect to pendent **14**
12. Female glumes hairy on the back, dark brown to blackish ..... (**C. haematostoma**)
+ Female glumes glabrous on the back, brown or red **13**
13. Female glumes red-brown, distinctly emarginate and with the midrib forming a long aculeolate mucro. Utricles obovate, distinctly ribbed, abruptly contracted into a short entire beak ..... (**C. cardiolepis**)
+ Female glumes brown, acute to slightly, ± obliquely emarginate or with a short glabrous mucro. Utricles lanceolate-ovate, gradually contracted towards both ends, not ribbed ..... **C. setosa**
14. Lower sheaths distinctly reticulate, ± red. Utricles small **15**
+ Lower sheaths fibrous, not distinctly reticulate, brown to black. Utricles usually larger **16**
15. Surface of utricles with prominent ribs. Female glumes with indistinct midrib. Lower sheaths very delicately reticulate ..... (**C. schlagintweitiana**)

© Biologiezentrum Linz/Austria; download unter www.biologiezentrum.at

\+ Utricles bordered with a narrow rim, otherwise without ribs. Female glumes with a prominent midrib of 3 incrassate nerves. Reticulation of lower sheath not as delicate ..... (**C. inanis**)
(Utricles with a long beak, female glumes with a long aculeolate mucro: **C. setigera**)

16. Plants forming a ligneous caudex. Female glumes reddish-brown. Utricles densely hirsute ..... (**C. koshewnikowii**)

16a Utricles large, 4-4.5 mm, female glumes c. 5 mm. Leaves broader. Plants large ..... (**C. koshewnikowii** subsp. **koshewnikowii**)

16b Utricles small, 3.5-4 mm, female glumes c. 4 mm. Leaves very narrow. Plants low ..... (**C. koshewnikowii** subsp. **chitralensis**)

\+ Plants not forming a ligneous caudex. Female glumes dull brown **17**

17. Utricles much flattened, ± contorted or with the margins involute, membranaceous or papery (sometimes ± hard when smutted) **18**

\+ Utricles trigonous or rounded, ± hard, membranaceous or coriaceous **19**

18. Utricles distinctly ribbed, ovate, gradually contracted to the base and into a ± long beak. Basal sheaths ± dissolute into fibres ..... **C. plectobasis**

\+ Utricles indistinctly ribbed, obovate, abruptly contracted into a short or indistinct beak. Basal sheaths remaining foliaceous ..... **C. alexeenkoana**

19. Leaves very broad. Beak of utricles long, with large spines on the margins. Plants densely tufted ..... **C. stenocarpa**

\+ Leaves narrower. Utricles with long or short beak, with small spines. Plants tufted to ± stoloniferous or rhizomatous **20**

20. Utricles 2.5-3 mm, smooth except for the margin of the short beak. Delicate plants with narrow leaves ..... **C. karoi**

\+ Utricles 3-5 mm long, ± covered with spines. More robust plants with broader leaves **21**

21. Plant rhizomatous. Utricles distinctly ribbed, c. 3.5 mm long, with beak 1 mm ..... (**C. kashmirensis**)

\+ Plant ± densely tufted or with elongate stolons. Utricles indistinctly ribbed on the faces of the body, 3.5-5.5 mm long, with beak 1-2 mm **22**

22. Utricles 3.5-4.5 mm, with beak 1-1.5 mm ..... **C. oligocarya**

\+ Utricles 5-5.5 mm, with beak 1,8-2 mm ..... (**C. alajica**)

23. Utricles flat, papery, gradually contracted into a short beak **24**

\+ Utricles solid, membranaceous or subcoriaceous **28**

24. Densely caespitose large plants. Utricles large, 5-8 mm long ..... **C. nivalis**

\+ Laxly caespitose, stoloniferous or rhizomatous, plants more delicate. Utricles smaller, 3.5-5.5 mm long **25**

25. Plants ± stoloniferous, with stolons densely covered with black dissolute scales. Utricles and glumes black to ± ferrugineous. Beak of utricle absent ..... (**C. montis-everestii**)

\+ Plants caespitose or rhizomatous, rhizomes not densely scaly. Glumes almost pure black, utricles black or yellowish. Beak of utricle short or long **26**

26. Plant caespitose. Utricles yellowish with a short black beak ..... **C. decaulescens**

\+ Plant rhizomatous. Utricles black except for the very base **27**

27. Beak of utricle short, up to 0.5 mm. Female glumes acute to shortly acuminate. Delicate plants ..... **C. atrofusca**

\+ Beak of utricle long, 1-1.5 mm. Female glumes with a long, setaceous tip. Robust plants ..... (**C. cruenta**)

28. At least the lowest spike long stalked, pendent **29**

\+ All spikes shortly stalked, not pendent **30**

29. Robust plants with very broad leaves. Utricles large, 4-6 mm, beak of utricles long, with large spines on the margins ..... **C. stenocarpa**

\+ Delicate plants with narrow leaves. Utricles small, 2.5-3 mm long, smooth except for the base of the short beak ..... **C. karoi**

30. Utricles ± coriaceous, shining brown, abruptly contracted into a ± long beak **31**

\+ Utricles membranaceous or papery, usually not shining, with or without beak **34**

31. Robust plant with cylindric female spikes ..... **C. songorica**

\+ Delicate plants with densely clustered, globose or ovoid female spikes **32**

© Biologiezentrum Linz/Austria; download unter www.biologiezentrum.at

32. Acaulescent with female spikes crowded at the base of the plant, male spike long stalked. Low alpine plants, c. 5 cm high ..... (**C. tangulashanensis**)
\+ Female spikes on distinct stem. Plant (5-) 10-70 cm high **33**
33. Stem c. 5-10 cm. Female spikes ± globose, densely clustered. Beak of utricle c. 1 mm ..... (**C. supina**)
\+ Stem c. 15-30 cm. Female spikes ovoid, shortly stalked and well separated. Beak of utricle c. 2 mm ..... (**C. turkestanica**)
34. Female glumes dark brown to black, with green midrib **35**
\+ Female glumes greenish to light brown **41**
35. Utricles abruptly contracted to a black mouth or a very short entire beak **36**
\+ Utricles gradually contracted into a distinct ± bifid beak **38**
36. Utricles smooth, papery, much flattened, lenticular ..... **C. decaulescens**
\+ Utricles minutely papillose, membranaceous, oval or trigonous in cross-section **37**
37. Utricles and female glumes large. Lower leaf sheaths red ..... (**C. duthiei**)
\+ Utricles and female glumes small. Lower leaf sheaths brown ..... **C. pseudobicolor** (cf. also **C. gracilenta**, **C. lehmannii**)
38. Female glumes black, much smaller than the utricles ..... **C. infuscata**
\+ Female glumes brown to black, large and usually covering the utricles **39**
39. Utricles with strong spines towards the beak ..... (**C. obscura**)
\+ Utricles papillose, tuberculate or with very small spines towards the beak **40**
40. Utricles rounded at base, contracted into a very short beak. Female glumes dark brown to black, with narrow hyaline margin. Leaves dull green, with a trigonous, moderately long tip, not pungent ..... **C. melanantha**
\+ Utricles stipitate at base, beak long. Female glumes ferrugineous to dark brown, with a broad hyaline margin. Leaves light green, tip very long and fine, pungent ..... **C. moorcroftii**
41. Utricles inflated, very large, attenuated into a long beak ..... **C. pamirensis**
\+ Utricles not inflated, smaller, with a short beak **42**
42. Female spikes short, ovoid, ± congested ..... **C. viridula**
\+ Female spikes cylindric, widely separated ..... **C. diluta**

* **Carex acutiformis** EHRH. 1789 - **A**: Kashmir: Ganderbal 1830 m, *T.Thomson* (CLARKE 1898). **D**: Temp. Eurasia. **N**: Reported from **Gilgit**, *Tanner* (Ann.Cat.Pak.), doubtful. The few specimens from Kashmir at K and BM are mostly too young to be definite. *C. acutiformis* occurs with certainty in NE Afgh.: Takhar Prov. 1150 m, *Podlech 10687* (hb. Podlech!).

* **Carex alajica** LITV. 1910 - **Ic.**: Fl.Tadzh.2: fig.27(4). **Fig. 2** (8). **A**: Kongur: Upper Oytag Vy. 3120 m, *Miehe 8666!*. Alai: Zaalaysky Mts.; Kaindy Vy. 3000-3900 m (Fl.Tadzh.). **D**: W Tian Shan, E Pamir (Alai, Kongur Shan). **E**: (Kongur:) Relatively humid *Picea schrenkiana* forests on loess slopes. **N**: Very close to *C. oligocarya* and perhaps better regarded as a subspecies of this.

A: W Pamir: Vrang [Pyandzh Rv.], *Ikonnikov* (Fl.Tadzh.); to be expected in the Afghan Wakhan. E Pamir: Chechekty Rv. [N of Murgab], *Ikonnikov* (Fl.Tadzh.). Deosai: Burji P., towards Deosai, *R.R.Stewart 20160* (Ann.Cat.Pak.: f. *lutea*). Deosai E 4550-4600 m, *Miehe 5111!* (typical and f. *lutea*); *5128!*. Zanskar: Lahul, Lingti, close to water 10000' [3050 m], 1941-06-29, *N.L.Bor* s.n. (K! **type**). Surichan P. - Kargiak 4900 m, 1993-07-27, *Holzner & Kriechbaum* s.n.!. Himachal Pr.: Bara Lacha P. 4880 m, *N.L.Bor* s.n. (K!); *Aswal 11001* (ASWAL & MEHROTRA 1994).

D: Endemic: Wakhan (Pyandzh Rv., Tadzhik side), E Pamir (rare), C. Karakorum (locally frequent), Inner W Himalaya: Deosai Plains, Upper Indus Vy., SE Zanskar, NW Lahul (apparently scattered and disjunct). *Endem.*

E: (4240) 4300-5030 (5250) m, alp. - subniv., scattered, but locally frequent in the high central ranges. Dry to relatively humid turf, on slightly inclined fine gravel up to the highest turf spots of the free gelifluction belt, where on the margins of open, rapidly moving frost scree dominant and community-building, often with *Kobresia karakorumensis* or *Colpodium baltistanicum*. "Quite common at above 14000' [4270 m], beginning to form carpets" (*Culbert 89*). Rare and very local in the lower alpine belt in shady water-surplus habitats.

N: A dwarf high alpine species, which probably represents one of the most distinctive Karakorum endemics. Although *C. borii* is locally quite common, it curiously was discovered very late, probably because it nearly always occurs at very high altitudes. Apparently, it has mostly a single terminal spike, but this is often ± lobed and better developed specimens have up to three distinct spikes. *C. borii* has close affinities to sect. *Aulocystis*. Hybrids probably occur with *C. alexeenkoana*. The occasional occurrence of straw-coloured spikes (f. *lutea* R. R. STEWART) is shared with species of sect. *Atratae* (e.g. *C. nivalis*). NELMES (1949) regarded *C. borii* as a monotypic section of "*Primocarex*", which at least appears not substantial. *Carex montis-everestii* KÜKENTHAL (see there) was confused with *C. borii* (Fl.Tadzh.; DICKORÉ 1991), probably because the type specimen is a similarly reduced plant. *Carex ursina* DEWEY, a high arctic species, shows a striking superficial resemblance to *C. borii*. It has, however, gynaecandrous spikes and two stigmas.

* **Carex brunnea** THUNB. 1784 - **Ic.:** KÜKENTHAL 1909: fig.102 A-E. **A**: Reported from Kashmir (Ann.Cat.Pak.). **D**: W Himalaya, India - SE Asia, Japan; Australia.

* **Carex canescens** L. 1753 (*Carex curta* GOOD. 1794) - **A**: Astor: Kamri P. N 3660 m, *R.R.Stewart 22703* (K!). Rama 3050-3350 m, *R.R.Stewart 22895; 22896* (K!). Deosai: *R.R.Stewart 20066* (Ann.Cat.Pak.). Hazara (Ann.Cat.Pak.). Kashmir: Burzil P. 3200 m, *C.B.Clarke 29630* (K!); Pahlgam 3660 m, *C.B.Clarke 31072* (CLARKE 1898; K!). Yamhar P. 3660 m, *C.B.Clarke 12462* (K!). Himachal Pr.: Sissu, *Bor 12387* (DD; ASWAL & MEHROTRA 1994). **D**: Temp. N hemisphere. **N**: Apparently rare in the W Himalaya.

© Biologiezentrum Linz/Austria; download unter www.biologiezentrum.at

* **Carex cardiolepis** NEES in WIGHT 1834 - **A**: Chitral. Swat: Shangla 2050 m, *Rechinger 30648* (W!). Hazara. Kashmir 2000-3300 m. Taulipir 2130 m, *A.Rashid & al. 25630* (BM!). **D**: E Afgh. (Khost, Jaji, Laghman, Kabul, Paktia, Nuristan), W Himalaya (Afgh. - Nepal), ? E Himalaya - ? SW China. **E**: Temperate forests (*Cedrus deodara, Abies webbiana, Quercus balloot*) and moist open slopes of the outer Himalaya. **N**: Although very distinct by its green-red female glumes, which are deeply emarginate with a long aculeolate mucro, it is frequently misidentified. The distribution of *C. cardiolepis* in the Himalaya therefore appears to be very uncertain. Almost certainly, it is not found N of the main Himalaya range. In the E Himalaya it is ± substituted by *Carex laeta* BOOTT 1858, and perhaps other species.

* **Carex cernua** BOOTT 1867 - **A**: Kashmir: Srinagar 1620 m, *Gammie* s.n.; *Falconer 1198* (KÜKENTHAL 1909). **D**: Himalaya, SE Asia (China, Japan).

28. Carex cruenta NEES in WIGHT, Contr. Bot. India 128. 1834

Carex atrofusca subsp. *minor* (BOOTT) KOYAMA 1975, non DICKORÉ 1991

Ic.: KÜKENTHAL 1909: fig. 91E-F. **Fig. 3** (8).

CS **Nubra/Upper Shyok:** Sassir P. 5360 m, *Meinertzhagen* s.n. (BM!).

A: Chitral: Lowari P. 2900 m, *Harris 16736* (BM!). Chilas: Kosto Vy., ridge above Jiliper High Camp 4200 m, *Nüsser 1328!;* Upper Kosto Vy., Jiliper High Camp 4210 m, *Nüsser 1433!.* Uppermost Pattaro Vy., Guttum Sagar - Kosto Gali 4830 m, *Nüsser 1407!.* Astor: Kalapani 3200 m, *Giles 121* (K!; CLARKE 1898). Das Kirim - Sardar Kothi 2740-3050 m, *R.R.Stewart 22003* (K!). Uppermost Rupal Vy. (Toshain Gah), ascent to Mazeno Gali moraine 5010 m, *Nüsser 1518!.* Deosai: Burzil P. - Deosai 3660-3960 m, *R.R.Stewart 22188* (K!). Zanskar: *T.Thomson* (CLARKE 1898). Swat. Hazara (Ann.Cat.Pak.). Kashmir: common (Ann.Cat.Pak.), 3050-3350 m. Kishenganga Vy., *Winterbottom 601* (K!). Burzil P. 1847-06-28, *Winterbottom 512* (K!); 1876-06-26, *C.B.Clarke 29616* (K!).; [?]4570 m, Gumbar [Zoji P.], *Jacquemont 988* (K!). Near Baltal, *Duthie 11622* (K!). Sonamarg 3350 m, *R.R.Stewart 9774* (K!). Khillanmarg 3050 m, *R.R.Stewart 8594A* (K!). Liddar Vy. 3350 m, *Drummond 14157* (K!). Rembiana Vy. 2440 m, *C.B.Clarke 27350* (K!). Pir Panjal, *Duthie 25771* (K!); 3350 m, *C.B.Clarke 28773* (K!). Margan P., *Meebold 2489*; Kishtwar (2440-4270 m), *T.Thomson* s.n. (KÜKENTHAL 1909). Himachal Pr.: Chotadhara-Batal, *Aswal 6901*; common (ASWAL & MEHROTRA 1994).

D: Himalaya (Chitral - SE Tibet). *Sino-Himal.*

E: 5360 m, subniv. rare in the SE. "Dry ground among rocks" (*Meinertzhagen*). (Generally:) Humid alpine meadows.

N: The Sassir P. locality does not seem to be typical according to the general ecology and chorology of *C. cruenta*. The species may have been introduced there along the Karakorum trade route, if the possibility of a wrong herbarium ticket can be excluded. *C. cruenta* furthermore is reported from Gilgit, Baltistan and Dras (Ann.Cat.Pak.), but no additional herbarium material has been found referable to the Karakorum proper. *C. cruenta* seems to be primarily a species of the (lower) Outer Himalaya, where it replaces *C. atrofusca*. Imperfect specimens are easily confused with *C. nivalis*.

29. Carex curaica KUNTH, Enum. Pl. 2: 375. 1837

N **Karakash:** Karakash Vy. 4270 m, *Henderson 367* (HOOKER 1894, CLARKE 1898). Abdul Gafuer Langar 4500 m, 1927-10-04, *Bosshard* (Z!; SCHMID 1932: "*C. pseudofoetida*").

Unloc.: Pamir region 3960-4270, *Alcock 17766* (K!). Yarkand Exp., 1870-07-30, *Henderson 210* (K!).

A: E Pamir 3800 m, rare (Fl.Tadzh.).

© Biologiezentrum Linz/Austria; download unter www.biologiezentrum.at

D: Siberia (Altai - Sajan), Mountains of C. Asia (Dzung. Alatau, N & C. Tian Shan, E Pamir, N Karakorum). *Centr.As.*
E: 3930-4820 m, subalp. (- alp.), rare in the N. Fens (*Carex pseudofoetida, C. orbicularis, Kobresia royleana*).
N: A poorly understood and doubtful taxon. Usually much larger than, but perhaps intergrading with *C. pseudofoetida* and difficult to distinguish from robust forms of this. There are some large plants in the south which may be better placed under *C. pseudofoetida*, such as the record: [Deosai] Devil's Plains 3200-4420 m, *C.B.Clarke 29626; 29842* (CLARKE 1898) [**Skardu:** Burji P. 4420 m, *C.B.Clarke 29842 = C. pseudofoetida* !].

30. **Carex decaulescens** V. KRECZ., Fl. URSS 3: 255, 599. 1935

Carex atrata auct. non L. 1753: B. FEDTSCH. p.p.

Ic.: Fl.Tadzh.2: fig.23(4-7).

subsp. **alsia** (RAYMOND) KUKKONEN, Ann. Bot. Fennici **21**: 387. 1984

Carex alsia RAYMOND 1965

Ic.: **fig. 3** (2).

W **Yasin:** Darkot SW side 3510 m, *Bowes Lyon 8110* (K!).
A: W & E Pamir 1600-3900 m (Fl.Tadzh.: *C. decaulescens*). Chitral: Khot An, N of Mastuj, between Turikho and Mastuj Rivers, 13000' [3960 m], on rock ledges, 1958-07-11, *Stainton 2839* (W! **holotype**, BM **isotype**). Chumarkhan P. E of Mastuj 3960 m, *Stainton* 2921 (W!).
D: Tian Shan, W Pamir-Alai (subsp. *decaulescens*); Chitral, W Gilgit: Yasin (subsp. *alsia*). *W Pamir.*
E: 3510 m, mont., rare in the extreme W. "In moist soil near stream" (*Bowes Lyon 8110*).
N: Critical, known only from a few collections. KUKKONEN's (1984) reduction to a subspecies of *C. decaulescens* has to be proved. *Carex decaulescens* subsp. *alsia* is similar to *C. infuscata* and *C. pseudobicolor* (see there), but differs by the flat, papery, smooth utricles (± membranaceous, turgescent, verrucose in *C. infuscata* and *C. pseudobicolor*). It is also close to *C. duthiei*, which is stronger in all its parts. **Carex caucasica** STEVEN 1813 (*Carex atrata* L. var. *caucasica* (STEVEN) BOOTT 1862, *Carex atrata* L. subsp. *caucasica* (STEVEN) KÜKENTHAL 1909) apparently is also close to *C. decaulescens*. A single specimen previously determined as *C. caucasica* from **Changchenmo** probably is a form of *C. melanantha* with whitish utricles.

* **Carex diandra** SCHRANK 1781 (*Carex mitis* BOECK. 1875) - **A**: W Pamir 3550 m (Fl.Tadzh.). Kashmir 1830-2130 m. **D**: Temp. N hemisphere, S to W Himalaya (Kashmir - Bhutan). **N**: Apparently rare in the Himalaya.

31. **Carex diluta** M. BIEB., Fl. Taur.-Cauc. **2**: 388. 1808

Carex aitchisonii BOECK. 1880, *Carex fissirostris* BOISS. 1884 non J. BALL. 1884, *Carex karelinii* MEINSH. 1901, *Carex aspratilis* V. KRECZ. 1935, *Carex extensa* auct. non GOOD. 1794: C. A. MEYER 1831, *Carex punctata* auct. non GAUDIN 1811: REGEL 1881

E: 2300-3660 m, mont. - (subalp.), scattered in the SW. Moist turf by springs and irrigation canals.

N: The *Carex norvegica* complex (*C. alpina* SWARTZ in LILJEBLAD, non SCHRANK) has been divided up variously. KALELA (1944) presents a detailed account on its variation. RAYMOND (1965a) supposes the complex to contain around 20 microspecies. The W Himalayan material, however, appears to be rather uniform. The distinction between (montane) plants with shortly beaked utricles (*C. infuscata*) and (subalpine-alpine) plants without a beak (*C. pseudobicolor*) fits well into an ecological concept, but is not necessarily specific. *C. decaulescens* appears to be well separated, but perhaps closely related to the *C. norvegica* complex. *C. pseudobicolor* seems to be a characteristic species of the inner dry W Himalaya, which is ± substituted by *C. gracilenta* BOOTT ex STRACHEY 1854 (*C. infuscata* var. *gracilenta* (BOOTT) KOYAMA 1958) in the C. and E Himalaya. The limits, however, are somewhat obscure throughout Nepal, where both species occur. There, *C. gracilenta* is possibly confined to the humid Outer Himalayas, and *C. pseudobicolor* mainly occurs in the Tibetan Himalaya. Records of *C. gracilenta* from Afghanistan (KOYAMA 1958) or its occurrence in the Karakorum appear rather unlikely. Some specimens with brown utricles may represent untypical *C. pseudobicolor* or even depauperate specimens of *C. melanantha* ?. *Carex norvegica* s.str. is said to occur northwards from Altai and Mongolia (Pl.As.Centr.).

* **Carex ivanovae** EGOROVA 1966 ("*ivanoviae*") - **Ic.:** Pl.As.Centr.3: fig.3(2). **A**: C.Kunlun: Przhevalsky Mts. 4200-4500 m, 1890-08-21, *Roborovsky*; Cherchen, 30 km SE Achan 4190-4260 m, 1959-06-04, *Li & al. 9413; 9427* (Pl.As.Centr.). **D**: NE & C.Tibet: C.Kunlun, Changtang, Tangula Shan. **Map**: Pl.As.Centr. 3: map 9. **N**: The species may be found in areas adjacent to the NE Karakorum. In habit close to a depauperate *C. stenophylla*, but with three stigmas; also similar to *C. melanantha* s.l. Originally referred to § *Lamprochlaeneae*, but with cladoprophylls and perhaps a member of § *Japonicae*.

© Biologiezentrum Linz/Austria; download unter www.biologiezentrum.at

N: A valuable account on the *C. melanantha* group is given by RAYMOND (1965). The species of the group in the extreme come very close to each other, and their variation on the Tibetan Plateau appears to be still insufficiently understood. *Carex praeclara* NELMES, a dwarf high alpine endemic of S and E Tibet, probably is the most distinctive species of the complex. *Carex sabulosa* TURCZ. from Mongolia and northern C. Asia is considered conspecific with the N American *Carex leiophylla* MACKENZIE by RAYMOND (1965). It is also close to the Tibetan endemic *C. moorcroftii*. *Carex melanantha* s.str., under our concept is still a very variable taxon. The Karakorum plants usually are rather stout and rigid and thus approaching *C. moorcroftii*. Specimens of the most humid SW Karakorum, the Outer W Himalaya and Kashmir often are rather lax, and may be referable to *C. regelii* C. B. CLARKE. It is impossible to separate them specifically, but *C. regelii* may be considered as a result of introgression from the Outer Himalayan *Carex obscura* NEES in WIGHT into *C. melanantha*. *C. melanantha* s.str. is substituted by the closely related *C. moorcroftii* E of a line from Yarkand across the Karakorum P. to Zanskar / Rupshu. The exact delimitation of both, though usually sufficiently distinct, is not quite clear; hybrids may occur in areas of contact (Yarkand, Upper Indus Vy. ?). On the Pensi P., *C. melanantha* was collected W, and *C. moorcroftii* E of the pass; a similar situation probably with *Calamagrostis stoliczkae* - *Calamagrostis pulchella*.

D: Circumarctic: N Eurasia (in the mountains S to Caucasus, Pamir-Alai, Karakorum, Himalaya, Tibet), N America, ?S America (Patagonia). *Holarct.*

E: 3650-4720 (5180) m, subalp. (-alp.), not common. Fens and turf by springs and flushes, (seasonally) wet or shallowly flooded places (*Carex orbicularis, C. pseudofoetida*), irrigated pastures, among *Kobresia schoenoides*-tufts in naka-moors.

N: The height of the plants is very variable and not suitable as a differential mark against *C. parva*. Some plants of *C. microglochin* have a culm length of 30-35 cm (*Dickoré 849*), whereas European, but also many Himalayan and Tibetan specimens are much smaller (5-15 cm). *C. microglochin* sometimes grows together with *C. parva*, but it is more continental in its distribution and occurs even in C. Tibet. Young specimens of *C. microglochin* may resemble *C. sagaensis* (*C. maritima* group), *Kobresia pygmaea* or even *Blysmus rufus*. There may be some affinities between either of these, and certainly a

© Biologiezentrum Linz/Austria; download unter www.biologiezentrum.at

close relationship between the *C. microglochin* group and *Kobresia* sect. *Hemicarex* (*K. pygmaea* group) does exist.

* **Carex montis-everestii** KÜKENTHAL 1934 - **Ic.: fig. 3** (4). **A**: Zanskar: Debring 4830 m, *H.Hartmann 4067!*. W Tibet: Shiquanhe - Aong Co (N 32°28' E 81°20'), 4900 m, *Miehe+9672a!;* (N 32°38' E 81°20') 4870-4950 m, *Miehe+9674!*. E Wuma (N 32°34' E 83°22') 4650-4660 m, *Miehe+9680b!*; 4800-5200 m, *Miehe+9679a!*. N Moincer (N 31°15' E 80°15') 5000-5280 m, *Miehe+9641a!; 9642a!; +9644a!*. **D**: S Tibet, Inner Himalaya. **E**: Humid alpine turf. **N**: *C. montis-everestii* differs from *C. borii* by the long subterranean, scaly rhizomes, usually well separated spikes with the lowest female spike usually long peduncled, and the utricles with a few small spines towards the beak. The spikes are highly congested, however, in the type specimen of *C. montis-everestii*: Mt. Everest, Camp I, in moraine 18200' [5550 m], 1933-07-02, *H.Wager* s.n. (B! **holotype**, K! **isotype**), as well as in *Hartmann 4067*, which makes it difficult to distinguish from *C. borii*. This probably led to confusion between both species in Fl.Tadzh. and DICKORÉ 1991. Presently, with abundant material of *C. montis-everestii* from the Lhasa region of S Tibet at hand, this appears to be a quite variable, usually much stronger species, which clearly belongs to sect. *Aulocystis* and sometimes is difficult to delimit against the *C. melanantha* group and *C. haematostoma*. The locality in NE Zanskar probably represents a western outpost of the species.

E: (3760) 4300-5300 (5490) m, alp. - subniv., locally common in the E Karakorum. Superficially dry sandy depressions, gravel slopes, permafrost swamps.
N: Certainly no good fodder plant due to its hard, pungent leaves, but occurring in considerable quantity in the most barren regions and reported to be a main fodder for the Tibetan ass (*Equus kiang*). HENDERSON & HUME 1873: "sometimes it was met with in patches of several acres, each plant being several feet apart from the adjoining ones. It was almost the only food for the baggage animals for more than a week. It is very locally distributed and is usually found on dry gravel slopes, often at a distance from water". "The commonest grass in this district. Very little of it in flower. Only two kinds of grass noticed this side of Lanik-La. The other, no. 823, is scarce." (*Deasy & Pike*). Recorded, probably in error, from Swat (KITAMURA 1964) [? *C. melanantha*].

D: Tian Shan, Pamir-Alai, Hindukush (Afgh.: Paghman, Bamian, Kunar, Nuristan), Karakorum, W Himalaya: Afgh. - Nepal. *W Centr.As.*

E: (2400) 3200-4880 (5180) m, alp., locally common. Block screes, community-building and stabilizing screes and moraines with higher contents of fine soil, in boulder-strewn alpine turf and in *Salix karelinii* scrub; by periodical water-courses. Forming characteristical tall-sedge communities, often with *Delphinium brunonianum* and other tall herbs.

N: Usually a very distinctive tall and stout sedge, with nodding female spikes which have short, black glumes and large flat, whitish utricles. *C. nivalis* certainly exhibits a large amount of variation and it has been divided into several taxa, which are sometimes regarded as good species (NELMES 1939; RAYMOND 1965). These include: *Carex olivieri* BOECK. (*Carex nivalis* BOOTT f. *cinnamomea* KÜKENTHAL), *Carex griffithii* BOOTT (*Carex nivalis* BOOTT f. *griffithii* (BOOTT) KÜKENTHAL), *Carex luteobrunnea* NELMES (*Carex lepus-aestatis* KOYAMA) and *Carex gilesii* NELMES. We cannot follow the segregation of these species, but further studies in the complex, including the closely related *C. atrofusca* - *C. cruenta* group, are desirable to resolve its variation, which perhaps is due to hybridisation and may result in subspecific segregation.

D: C. Asia, Siberia, Mongolia; Altai, Tian Shan, Pamir-Alai, Hindukush, Karakorum, Kashmir, Himalaya (Afgh. - Nepal), Tibet, Qinghai (subsp. *orbicularis*). **Map:** Pl.As.Centr. 3: map 7. *Centr.As.*

E: (2800) 3170-4100 (5120) m, subalp. (-alp.), scattered, locally common. Wet habitats: community-building in flushes and fens, on margins of *Kobresia schoenoides* naka moors, in *Salix pycnostachya* scrub (with *Carex melanantha, C. microglochin*). Dwarf forms in moist grazed turf, on lake-shores and between *Kobresia schoenoides* tufts.

N: The very variable taxon is treated and discussed in a wide species-concept in Pl.As.Centr. (see for synonyms). The Karakorum plants represent subsp. **orbicularis**. *Carex orbicularis* BOOTT subsp. *kotschyana* (BOISS. & HOHENACKER) KUKKONEN 1984 (*Carex kotschyana* BOISS. & HOHENACKER 1854) is a western plant, occuring from Turkey to Iran: Semnan, Kerman, Luristan (KUKKONEN 1984). *Carex orbicularis* BOOTT subsp. *hissarodarvasica* OVCZ. & CZUK. 1963, from W Pamir appears to be somewhat intermediate between these.

D: Mongolia, Dzung., Tian Shan, Pamir-Alai, Afgh. (Bamian: Koh-i-Baba), Kashgaria, Karakorum, S Tibet, Himalaya, China. *Centr.As.*

E: 3650-3800 m, subalp., rare. Fens and wet turf (*Carex orbicularis*), among *Kobresia schoenoides* tufts. Often with *C. microglochin*, but perhaps preferring more humous situations with ± constant water-supply.

N: The racheola does not protrude from the 7-8 mm long utricles in *C. parva*, whereas it is exserted even at a very young state from the c. 5 mm long utricles in *C. microglochin*. Ecologically, the requirements of both species are rather similar, but *C. parva* appears to be confined to localities with a more constant and less salty water-supply. Accordingly it is not reported from C. Tibet.

D: Altai, Tian Shan, Pamir-Alai, Kashgaria, Kunlun, Hindukush, Karakorum, W Tibet, Himalaya (Afgh. - Bhutan), ?SE Tibet (subsp. *pseudofoetida*). **Map:** Pl.As.Centr.3: map 6. *W Centr.As.*

E: (3530) 3600-4910 (5180) m, (subalp.) - alp., common in the N, scattered to locally frequent in the W & S, rare in the E & C.Karakorum. Alpine turf and steppes on moraines, gravel and deflation pavements, up to the lower subnival belt (*Carex borii*), locally dominant on somewhat wet periglacial turf. Zonally lacking in the most continental areas (Mustagh Ata, K2-North), but present and also sometimes dominant in subalpine groundwater habitats, turf on riverside sands and in fens (*Kobresia schoenoides, Carex microglochin, Blysmus compressus*).

N: The complex around **Carex maritima** GUNN. 1772 (*Carex incurva* LIGHTF. 1777; non *Carex maritima* O. F. MUELLER 1777) is a most difficult one in Tibet and presents an extensive variation, but few clear-cut characters. Although the three taxa distinguished here (*C. curaica, C. pseudofoetida, C. sagaensis*) usually appear to be distinct, they may represent little more than extremes of a very wide eco-geographical variation. *C. pseudofoetida*, a widespread plant of alpine turf and subalpine flushes, is substituted by the dwarf *C. sagaensis* on the high alpine Tibetan Plateau. On the other hand, *C. curaica* is a tall plant which occurs in flushes of the most continental inner Karakorum ranges. Although still very variable in its dimensions, the vast majority of the specimens from the Karakorum and adjacent regions as cited above match exactly the type of *C. pseudofoetida*: [NE Iran, Prov. Kerman,] Kuh-i-Lalesar, in regione alpina, 3600 m, 1892-07-16, *Bornmüller 4801* (B! **holotype**). The **type** of *Carex pseudofoetida* KÜKENTHAL subsp. *afghanica* KUKKONEN 1984: from Wakhan probably belongs to *C. enervis* (see there), and at least is different from the Karakorum plants. **Carex pseudofoetida** KÜKENTHAL subsp. **acrifolia** (V. KRECZ.) KUKKONEN 1984 is a western plant, which occurs from Caucasus to the Elburz Mts. (KUKKONEN 1984). The circumarctic *C. maritima* GUNN. (*C. incurva* LIGHTF.), **Ic.: fig. 1** (6), differs in the suborbicular female bracts and larger utricles. Records of this from the Himalaya, Karakorum and Tibet may refer to *C. pseudofoetida* or *C. sagaensis*. *C. stenophylla* usually grows at lower altitudes, but its delimitation against *C. pseudofoetida* sometimes also presents problems. Records of *C. pseudofoetida* from **Biafo** of HARTMANN (1966), partly corrected by HARTMANN (1984), are here transferred to *C. stenophylla*.

* **Carex psychrophila** NEES in WIGHT 1834 - **Ic.**: KÜKENTHAL 1909: fig.97 A-E. **A**: Chitral: Shishi Gol, E of Drosh 2130 m, *Stainton 2378* (W!). Zanskar 2440-3660 m, *T.Thomson* (C. B. CLARKE 1898). Kashmir (common). **D**: Himalaya (Kashmir - W China). **N**: Primarily a plant of the humid outer Himalaya. A record from **Gilgit** (Ann.Cat.Pak.) probably is erroneous since a specimen under this name is *C. infuscata*.

* **Carex remota** L. subsp. **stewartii** KUKKONEN 1984 - **Ic.**: KUKKONEN 1984: fig.4b. **A**: Chitral. Swat: Near Kulali 6000' [1830 m], 1952-08-19, *R.R.Stewart 24557* (RAW **type**; KUKKONEN 1984). ?Hazara. ?Kashmir. **D**: W Himalaya: Afgh. (Nuristan) - NW India (Uttar Pradesh: Garhwal). **N**: **Carex remota** L. subsp. **remota** is reported to occur eastwards to Iran: Khorasan (KUKKONEN 1984). **Carex remota** L. subsp. **rochebrunii** (FRANCHET & SAVAT.) KÜKENTHAL 1909 (*Carex rochebrunii* FRANCHET & SAVAT. 1879; *Carex remota* L. var. *rochebrunii* (FRANCHET & SAVAT.) C. B. CLARKE 1878, *Carex monopleura* V. KRECZ. 1937) occurs in the C. & E Himalaya (Nepal - SE Tibet), China, Japan.

Changtang: Lungmo Co 5100-5350 m, *Miehe 8053!; 8117!; 8191!; 8196!*.

D: Tibet: W (NE Karakorum, Changtang), C. (Tangula Shan), S & SE (Upper Tsangpo Vy., Nyainqentanglha Shan, Tibetan Himalya: Yamdruk, Pomo Co, Lhünze); imperfectly known. *Tibet.*

E: (4130) 4650-5250 m, subniv., locally common in the extreme E Karakorum / Tibetan Plateau. Alpine desert (*Kraschenninnikovia compacta*) on permafrost slopes, usually on slightly inclined, often salty, water-saturated patterned ground, often forming one species-aggregations; in flushes (*Kobresia pygmaea*).

N: A tentative determination, since the variation of the recently described taxon and its relation to other species of the *C. maritima* complex is unknown. *C. sagaensis* comes very close to the circumarctic *Carex maritima* GUNN., but differs in the smaller utricles which are ± toothed towards the short beak. The specimens from NE Karakorum, West Tibet, and others from Tangula Shan and Nyainqentanglha Shan (leg. *Dickoré*) are usually distinct, but sometimes difficult to distinguish from *C. pseudofoetida*, and they perhaps intergrade (NE Karakorum ?) with this species.

* **Carex sanguinea** BOOTT 1846 (*Kobresia sanguinea* (BOOTT) RAYMOND 1965 - **A**: Swat: Khawazakhiela - Shangla (1300-1900 m), *Rechinger 30598* (W!). ?Hazara. Kashmir. **D**: W Outer Himalaya: Afgh. (Kurram, Laghman, Nuristan) - N Pakistan, Kashmir. **N**: Superficially close to *Kobresia laxa*, and occasionally confused with this.

* **Carex schlagintweitiana** BOECK. 1888 (*Carex setigera* D. DON var. *schlagintweitiana* (BOECK.) KÜKENTHAL 1909 *Carex inanis* KUNTH var. *schlagintweitiana* (BOECK.) KOYAMA 1978) - **A**: Hazara. Kashmir: 2130-2440 m. Banihal P., *Henderson 249* (K!; "*C. haematostoma*"). Near Taulipir 2130-2440 m, *R.R.Stewart 25627* (BM!). **D**: W Himalaya (Hazara, Kashmir, - Kumaon). Himachal Pr.: *Schlagintweit 5050* (BM! **type**). **N**: A species of the humid Outer Himalaya. The record from Yarkand (KÜKENTHAL 1909) is erroneous, since the specimen (Yarkand Exp., *Henderson 249*) was collected in Kashmir. *C. schlagintweitiana* is closer to *C. inanis* than to *C. setigera*, but differs specifically from both.

* **Carex setigera** D. DON 1824 - **A**: Reported from Kashmir. **D**: Himalaya (Kashmir - Bhutan).

46. Carex setosa BOOTT, Illustr. Carex **3**: 108, pl. 327-329. 1862

W **Gilgit:** Naltar Lakes 3350 m, *R.R.Stewart 26931* (BM!); 3660 m (K!). Naltar Vy., above Bichgari 3120 m, *Schickhoff 23!*.

Himachal Pr.: Lahul, Koksar 3660 m, *Bor 12269* (DD, K!; ASWAL & MEHROTRA 1994). W Chota Dara 3800 m, 1993-08-07, *Holzner & Kriechbaum* s.n.!.

D: Himalaya (SW Karakorum, Hazara, Kashmir - Sikkim), ?SW China. *W Himal.*

E: 3120-3660 m, subalp., rare. *Pinus wallichiana* forest (*Schickhoff 23*), probably extrazonal water-surplus habitats. On humid alpine turf and moist rock ledges in Kashmir.

N: Although this widespread Himalayan species is usually very distinct by its narrow spikes with red-brown female glumes, it shows some variability. Plants from the W part of its distribution area usually have less distinctly and shorter beaked utricles with a shorter, denser indumentum than the type. It occurs together with *C. karoi* in the Karakorum; both species are very similar in habit. *C. karoi* may be distinguished by the paler glumes and the utricles which are hairy only along the beak.

? 47. Carex songorica KAR. & KIR., Bull. Soc. Nat. Moscou **15**: 525. 1842

Carex fedtschenkoana KÜKENTHAL 1910, *Carex heterostachya* auct. non BUNGE 1832: KÜKENTHAL 1909

Ic.: Fl.Desert.Sin.1: fig.58(9-11).

CS **?Baltoro:** Paiju 3480 m, *H.Hartmann 284* (Z!); *285!* (HARTMANN 1966: "*C. pamirensis*").

A: E Pamir (Fl.Tadzh.). Astor: Kalapani 3010 m, *Schickhoff 1287!*. Dras: Dras Vy., below Matayan 3050-3350 m, *Duthie 13702* (BM!, K!; CLARKE 1898). Suru: Paskyum 2830 m, *B.B.Osmaston 19* (K!). Kashmir: Gurais - Burzil 2440-2740 m, *C.B.Clarke 29484; 29605* (BM!, K!; CLARKE 1898).

D: Caucasus - Siberia, Mongolia; Tian Shan, Pamir, Afgh. (Bamian, Parwan, Baghlan, Takhar, Kabul, Kunar), S Karakorum, SW Ladakh, Kashmir. *Ir.-Tur.*

E: ? 3480 m, mont., rare in the S Karakorum. Wet habitats.

N: The specimens *Hartmann 284; 285* are referred to here on account of the small (2.5 mm long), shortly beaked utricles. The material, however, is too young and not typical. *C. songorica* is common in many parts of Afghanistan. It seems to intergrade locally with *C. pamirensis* where both species come into contact.

E: 3630-4850 m, alp., locally common in the SW, rare in the central ranges. A dominant species of the relatively humid belt of closed alpine turf (*Kobresia nitens*), occasionally descending to the *Betula jacquemontii* forest. "Forming tufted meadow on earthy slopes, dominant" (*Polunin 6301*), "steep grassy slopes" (*Nasir & Webster 6249*). The species seems to be a main alpine fodder-plant in the SW Karakorum. Its bright olive-green colour is very characteristic from a distance.

N: *Carex longicuspis* BOECK., Cyper. Novae 1: 49. 1888 may be the oldest name for the taxon, but the type was apparently lost. BOECKELER's description is too inadaequate to prove this identity. Records of *Carex stenocarpa* of PODLECH & ANDERS 1977 (in part ?) and DICKORÉ 1991 are misidentifications of *C. alexeenkoana*.

D: Continental Eurasia: E Spain and N Italy (very local), SE-Europe - temp. Asia - Korea (*C. stenophylla*; the closely related *C. eleocharis* in N America). Subsp. **stenophylloides** (V. KRECZ.) IVANOVA: Turkey, Caucasus, N Iran, Afgh., S Kasakh., Kopet Dagh, Pamir-Alai, Tian Shan - W Mongolia; Kashg., Karakorum - S Tibet. **Map:** Pl.As.Centr.3: map 5 (*C. stenophylloides*). *Euras.*

E: (2730) 3050-4650 (5310) m, (mont.-) subalp. (-alp.), generally not common, frequent in the NW. Subalpine *Artemisia brevifolia* scrub-steppes and desert-steppes *(Oxytropis microphylla, Artemisia pamirica)*, up to lower alpine steppes, rarely in extremely dry *Krascheninnikovia ceratoides-Stipa glareosa* semideserts, where restricted to water surplus habitats (gravel fans, periodical water-courses). Often on well drained and not too compact soils of moraines, gravel fans, or on rapidly weathering silts, but usually not in pronounced ground-water habitats.

N: The widely distributed species had been split into numerous taxa. RAYMOND (1965) gives a valuable account on its classification. The N American *C. eleocharis* BAILEY (*C. stenophylla*

© Biologiezentrum Linz/Austria; download unter www.biologiezentrum.at

WAHLENB. subsp. *eleocharis* (BAILEY) HULTÉN) seems to be the best defined taxon of the group. Incomplete specimens of *C. stenophylla* may be recognised by the relatively slender rhizomes, the well developed and very delicate root system, and the rather narrow and relatively many leaves. Reduced forms of *C. stenophylla* may be confused with *C. divisa*. The morphologically similar *C. pseudofoetida*, which occurs on alpine turf and in subalpine groundwater habitats acts as an "altitudinal vicariant" of *C. stenophylla*. Unconfirmed records of *C. stenophylla* from above 4500 m are generally doubtful, and may often refer to *C. pseudofoetida*. However, *C. stenophylla* ascends to very high altitudes in SE Ladakh, where it was found on black slates (*H.Hartmann*, pers. comm.) as high as 5310 m. *Kobresia hyalinolepis* BOECK. 1888 is cited from: Ladakh, Zanskar, Spiti, *Schlagintweit 1154; 1862; 6953; 7180* (BOECKELER 1888). A record of *C. stenophylla* from [?]**Karakash:** Head of lower Karakash Vy. 4270-4570 m (HENDERSON & HUME 1873), may belong to *C. curaica*.

* **Carex supina** WAHLENB. 1803 - **A**: W Tibet: Burang Vy., Nepal - Tibet border (N 30°09' E 81°18') 4570 m, *Miehe+9619a!;* 4500-4600 m, *Miehe+9631a!*. **D**: Temp. Eurasia. **N**: Including probably minor segregates (*Carex aridula* V. KRECZ. 1946, *Carex korshinskyi* KOMAROV 1901, *Carex minutiscabra* KÜKENTHAL ex V. KRECZ. 1935), the (collective) species occurs widely scattered around the Tibetan Plateau in Dzungaria, Tian Shan, Inner Central Himalaya and S, E & NE Tibet.

* **Carex tangulashanensis** Y. C. YANG 1980 - **Ic.**: YANG 1980: fig.2. **A**: Kongur: Upper Oytag Vy. 3900 m, *Miehe 9141!*. W Kunlun: Tiznap Vy., W Kudi 3970-4340 m, *Miehe 8422!; 8456!; 8474!*; Upper Tiznap Vy. 4220-4370 m, *Miehe 7556!* (veg.); *7586!* (veg.); *7593!* (veg.). **D**: E Tibet, Tangula Shan (Upper Yangtse, Upper Mekong, Upper Salween): Yushu 4750 m; Zadoi (YANG 1980); Wenquan - Yanshiping 4800 m (leg. *Dickoré*); Nagqu - Denqen 4600 m (leg. *Dickoré*); W Kunlun (new!); C. Tian Shan: Urumqi - Shengli Daban 3700 m (new: leg. *Miehe 9036!*). **E**: (Kunlun:) 3900-4370, alp., rare. Steppe-turf on loess-covered slopes (*Carex alexeenkoana, Kobresia capillifolia, K. kashgarica*), apparently preferring S-exposition. **N**: Very distinct morphologically by its low creeping habit with the female spikes crowded at the base and a single long stalked male spike. Although the new localities in the W Kunlun are some 1400 km distant from those of the Tangula Shan, no morphological differences can be found. The Tian Shan locality again gives a large extension of the species' area of distribution. The dwarf and ecologically highly specialized high alpine species may be hitherto overlooked and is to be expected in the high mountain ranges around the Tarim basin. In the W Kunlun, *C. tangulashanensis* seems to be confined to a narrow belt of rather humid alpine steppe-turf of the loess covered northernmost ranges (mainly on S-facing slopes), together with other "relict" species (*Kobresia kashgarica, Viola tianschanica, Oxytropis melanocalyx*).

* **Carex turkestanica** REGEL 1880 (*Carex nitida* auct. non HOST: ? B. FEDTSCH., *Carex nitida* HOST var. *aspera* KÜKENTHAL 1909) - **Ic.**: Fl.Tadzh.2: fig.28(7-10). D: Turkestan, Hindukush, (C. E, NE Afgh.), W Himalaya (Chitral - Kumaon). *W Himal.*
E: 3660-3960 m, subalp., rare (SW Karakorum). Wet habitats.
N: *C. wendelboi* is a xerophytic form which, except for the relatively short lower bract and the slightly (not significantly) smaller utricles, is identical to *C. vulpinaris* (*Royle 73* K! **type**).

Putative hybrids (hybrids in *Carex* are mostly sterile and thus usually not recognized with certainty among scanty or insufficient material; some of the putative hybrids are therefore cited under the respective parent to which they come closest):

Carex alexeenkoana X C. borii (*Carex haematostoma* NEES var. *submacrogyna* auct. non KÜKENTHAL 1909: DICKORÉ 1991)

CN **K2-North:** K2-N Gl. E 4750 m, *Dickoré 677!*; 4800-4920 m, *Dickoré 786!*.
N: Found in two populations on the nunatak between Upper K2-N and Skyang Kangri Glaciers. Alp. - subniv. turf spots on stable, slighly inclined gravel *(Carex borii* [common], *C. alexeenkoana* [rare], *Stipa concinna, Viola kunawarensis, Potentilla pamirica*) on the lower margin of the free gelifluction belt. The plant is ± intermediate between the putative parents (which are of a very different habit !). Although the utricles appear to be sterile, the plant forms a quite extensive population, probably by means of its stolons.

Carex atrofusca X C. pseudobicolor ?

Carex atrofusca X C. nivalis ?

Both hybrids may rarely occur among populations of the putative parents in a few locations of **Gilgit** and **Hunza**, but the material is too young to come to a definite conclusion.

Carex melanantha X moorcroftii ?

Fertile plants which apparently combine the characters of the closely related vicarious species locally occur in the areas of contact.

Carex melanantha X orbicularis ?

There is some confusion in the determination of both species, which often occur together. Usually they are well defined, but sometimes they are completely alike and a few specimens apparently combine 2 and 3 stigmas on the same plant.

© Biologiezentrum Linz/Austria; download unter www.biologiezentrum.at

Carex oligocarya X plectobasis ?
It may locally occur in the SW Karakorum where both species come into contact.

Carex pseudofoetida X sagaensis ?
Fertile plants which combine the characters of the closely related vicarious species locally occur in the areas of contact. - **Carex curaica X C. pseudofoetida ?** is another possible hybrid.

52. Cladium mariscus (L.) POHL, Tent. Fl. Bohem. 1: 32. 1809

Schoenus mariscus L. 1753

A: S Tadzh. 500-900 m (Fl.Tadzh.). Kashmir: "Circa urbem Kashmir", *Jacquemont 645* (K!). Srinagar 1580 m, *C.B.Clarke 29075* (K!). Pir Panjal, Nil Nag 1830 m, R.R.Stewart 23060 (K!).
D: Trop. - temp. regions. *Cosmopol.*
E: c. 2400 m, coll. - mont., rare in the SW. (Generally:) Wet habitats, swamps or on the borders of lakes.
N: No specimen seen from the Karakorum, but not likely to be confused.

Cyperus (see also *Pycreus*):
Little material of *Cyperus* s.l. was available for the present study. Most species are lowland plants of wet habitats, only occasionally found in the deep valleys of the S & W Karakorum. The following treatment is not satisfactory and most literature records have to be confirmed. A more thorough examination with the specimens at hand, may result in a further reduction of the number of reported species. Other species, however, may be found in the field, or introduced into the Karakorum with the increasing traffic.

Eleocharis:

A provisional treatment of a critical genus. The complex of *E. palustris* is still insufficiently known in C.Asia, and the delimitation of taxa within the aggregate is ± tentative.

Key to *Eleocharis*:

1. Stems capillary, 4-angled. Spikelet 2-4 mm long. Nut longitudinally ribbed ..... (**E. acicularis**)
\+ Stems stout, terete. Spikelet 4-30 mm long. Nut smooth or faintly striate **2**
2. Style-base not clearly demarcated from the nut, not or scarcely constricted at the base. Spikelet with 2-8 flowers ..... **E. quinqueflora**
\+ Style-base usually swollen and constricted at the base, clearly demarced from the nut. Spikelet with more than 8 flowers **3**
3. Stem septate, very thick, > 3 mm in diameter. Rhizomes with large tubers ..... (**E. dulcis**)
\+ Stem weaker, < 3 mm in diameter. Rhizomes without tubers **4**
4. Only the lowest glume of the spikelet empty, encircling base of spikelet **5**
\+ Two lowest glumes of spikelet empty, subequal, and each half-encircling base of spikelet **6**
5. Style-base minute, c. 1/4 as wide as nut. Lowest glume up to 1/2 as long as spikelet. Stem weak, easily cracked ..... (**E. oxylepis**)
\+ Style-base at least 1/3 as wide as nut. Lowest glume rarely more than 1/3 as long as spikelet. Stem firm ..... **E. uniglumis**
6. Style-base longer than wide. Bristles 0-4 ..... **E. palustris**
\+ Style-base mitriform, wider than long. Bristles 4(-5) ..... (**E. argyrolepis**, **E. mitracarpa**)

* **Eleocharis acicularis** (L.) ROEMER & SCHULTES 1817 - **A**: Wakhan: *Paulsen 1454* (C; KUKKONEN 1990a: an outlying and much doubted, but authentical record). **D**: Circumarctic: Eurasia (S to Caucasus, Wakhan, Dzungaria, N Mongolia), N America.

* **Eleocharis argyrolepis** KJERULFF ex BUNGE 1851 - **Ic.**:Fl.Desert.Sin.1: fig.54(5-8). **A**: Reported from N Kashg.: Maralbashi 1070 m, 1932-06-14, *Persson 258* (PERSSON 1938); Kongur: Bostan-terek 2400 m, 1934-08-14, *Persson 611* (PERSSON 1938). **D**: Dzungaria, Kashgaria, Tian Shan, Pamir-Alai. **N**: Close to *E. mitracarpa*.

Kobresia:

Kobresia-species form an important part of the alpine vegetation of the Karakorum. Although the species are usually well defined, the plants are generally very plastic in their vegetative morphology and the differential characters are often rather subtle. Literature records are often not interpretable, because of frequent misidentifications of scarce or juvenile material.

Synopsis of *Kobresia* (CLARKE 1883, KÜKENTHAL 1909, IVANOVA 1939):

Sect. *Pseudocobresia* KÜKENTHAL: *K. macrantha*

Sect. *Hemicarex* (BENTHAM) C. B. CLARKE: *K. pygmaea*

Sect. *Elyna* (SCHRADER) C. B. CLARKE: *K. capillifolia*, (*K. kashgarica*), (*K. filifolia*), *K. nitens, K. robusta, K. schoenoides*

Sect. *Kobresia*: (*K. humilis*), *K. karakorumensis, K. laxa*, (*K. persica*), (*K. pusilla*), *K. royleana*

K. laxa is sometimes (IVANOVA 1939) included into the genus *Schoenoxiphium*. It seems, however, to be also closely related to *K. royleana*. The monotypic genus *Blysmocarex* was established on *Kobresia macrantha* by the same authority. This may be substantial for phylogenetic reasons.

Key to *Kobresia* of the Karakorum:

1. Rhizomatous, stigmas two ..... **K. macrantha**
+ Usually densely tufted plants, rarely stoloniferous; stigmas mostly three, sometimes two (but then densely tufted) **2**
2. Lower dead sheaths without leaf-blades, brown to black, shining; leaves linear-subulate to navicular or flat, but not distinctly plicate; inflorescence a narrowly cylindric to ovate spike, rarely proliferating ... **3**
+ Lower dead sheaths with leaf-blades, dull to shining brown; leaves broader, flat, folded. Inflorescence a panicle or an ovoid spike **8**

3. Inflorescence few(2-5)-flowered. Plants very dwarf, 1-4 cm high, stems shorter than leaves ..... **K. pygmaea**
+ Inflorescence a many-flowered spike. Plants usually higher than 5 cm, stems often exceeding the leaves 4
4. Inflorescence a narrow spike, rarely lobed in the lower part; stems weak, leaves subulate 5
+ Spike broadly cylindric to ovoid; stems weak or stout, leaves subulate or linear-lanceolate 6
5. Glumes long, dark brown to black. Nut (excluding beak) c. 2.5-3.5 mm, distinctly reticulate on surface, ripe nut falling naked, the open prophyll not separating from the axis; male flowers two ..... **K. capillifolia**
+ Glumes short, greenish-cinnamon. Nut (excluding beak) c. 1.8-2.3 mm, very faintly reticulate; prophyll fused in the lower third, easily separated from the axis, enclosing and falling together with the ripe nut and the single male flower ..... (**K. kashgarica**)
6. Stems very stout, 1-2 mm thick; leaves linear-lanceolate, oval to navicular in cross-section. Prophylls open; glumes entirely brown with hyaline margin ..... **K. schoenoides**
+ Stems < 1 mm thick, leaves subulate. Prophylls closed to at least half of their length; glumes with prominent green midrib 7
7. Glumes with a narrow hyaline margin (up to 0.5 mm wide). Spikes ovoid. Leaves ± soft ..... **K. nitens**
+ Glumes with a broad (c. 1 mm) hyaline margin. Spikes narrowly ovoid to cylindric. Leaves rigid ..... **K. robusta**
8. Plants weak, with short stolons, not densely tufted; basal leaves scarcely recurved ..... **K. laxa**
+ Plants stout, densely tufted; basal leaves often strongly recurved 9
9. Stigmas 2; nut flat, without ribs, with a very short, broad stylopodium. Prophylls shortly ovate, with two faint keels; spikelet with 2 male flowers (+ 1 sterile). Inflorescence a short spike. Plants low, cushion-forming ..... **K. karakorumensis**
(**K. pusilla**: beak of nut longer, male flowers 3-4)
+ Stigmas 3, nut triangular-ovate in cross-section, with three prominent longitudinal ribs, with a long beak. Prophylls obliquely 2-keeled, one of which incrassate and spiny on the back; spikelet with 1 male flower (+ 1 sterile). Inflorescence nearly always lobed, paniculate. Plants dwarf to very tall ..... **K. royleana**
(**K. humilis** differs in having a single spike, somewhat narrower leaves and nuts with shorter beak).

D: ?Caucasus (*K. macrolepis* MEINSH.); Pamir-Alai, Tian Shan, ?Altai, ?E Siberia; Karakorum, W Kunlun, W Himalaya: E Afgh. (Kurram, Nuristan) - Nepal, ? W, S & E Tibet (Qinghai, Xizang), ? W China (Gansu, Sichuan). **Map:** IVANOVA 1939: map 2 (*K.capillifolia, K. capilliformis*). Pl.As.Centr.3: map 2 (*K. ovczinnikovii, K. capilliformis*). *Centr.As.*

E: (3190) 3420-4950 m, alp., locally common. *Salix karelinii* scrub, meadows and alpine turf, usually rather stable gravel slopes (granite) with more or less frost activity and solifluction. In the driest areas ± restricted to groundwater-habitats on N-facing slopes of the upper alpine and subnival belt (flushes, margins of naka-moors; *K. schoenoides*). *K. capillifolia* forms large mats, which are connected by its dead sheaths and give a very hard sod. This community resembles the Elynetea-communities (*Kobresia myosuroides*) of the European Alps. *K. capillifolia* is also common in the C. Tian Shan (Urumqi Vy., Shengli Daban, leg. *Miehe*), where it occurs from the upper forest belt (*Picea schrenkiana, Betula*) to the highest alpine turf.

N: The species is very variable in all of its dimensions and has been divided up variously. OVCZINNIKOV (1963) in Fl.Tadzh.2 distinguishes *Kobresia capillifolia* (DECNE.) C. B. CLARKE subsp. *capilliformis* (IVANOVA) OVCZ. and *Kobresia capillifolia* (DECNE.) C. B. CLARKE subsp. *pamirica* OVCZ. (*K. capilliformis* IVANOVA p.p.). These taxa represent hardly more than ecological variants; and the specimens cited above, as well as most of material seen from Pamir and Tian Shan

© Biologiezentrum Linz/Austria; download unter www.biologiezentrum.at

must be considered typical. A different plant (*K. kashgarica*), apparently combining characters of some of the previously described subspecies of *K. capillifolia*, but which is also close to *K. myosuroides*, occurs at high altitudes of the Kunlun Shan N slope and of the Central Tian Shan. *Kobresia macrolepis* MEINSH. 1900, from the Caucasus, is close to *K. capillifolia*, but may be a distinct species (cf. KUKKONEN 1990b). The distribution of *K. capillifolia* towards Tibet is very uncertain, due to frequent misidentifications.

* **Kobresia duthiei** C. B. CLARKE in HOOKER f. 1894 (*Kobresia rostrata* C. B. CLARKE ex IVANOVA 1939 - **A**: ?Kashmir. Himachal Pr. (ASWAL & MEHROTRA 1994). **D**: W Himalaya: ?Kashmir, Himachal Pr. - Sikkim.

Ic.: fig. 4 (1).

Diagnosis

Differt a *K. pusilla* perigyniis brevioribus basi connatis, nuce minore 2,4-2,7 mm (nec 2,7-3,2 mm) in styli basin cylindricam subsensim abiente (nec abrupte contracta), spiculis partialibus androgynis floribus masculis 2 (nec 2-4), glumis ovatis 2,5-3 mm longis (nec 3-4 mm) brunneis anguste hyalino-marginatis (nec obovatis late hyalino-marginatis). Differt a *K. persica, K. humile, K. royleana* stylibus 2 (nec 3).

Descriptio

Rhizoma dense ramificatum, lignosum. Planta caespitem nanum formans.

Culmus (2) 3-15 (20) cm altus strictus rigidus obtusangulus striatus superne triqueter laevis.

Folia culmo breviora conferta 1-2,5 mm lata, plana, rigida. Vaginae basilares brunneae foliiferae ± recurvatae.

Spicula solitaria (raro composita) breviter cylindrica 5-12 mm longa 2-4 mm lata.

Spiculae partiales androgynae 3-4-florae, flos basilaris femineus, flores superiores 2 masculini (1 sterilis).

Glumae ovatae, 2,5-3 mm longae, obtusae, brunneae, anguste hyalino-marginatae.

© Biologiezentrum Linz/Austria; download unter www.biologiezentrum.at

Perigynium squamam aequans, ellipticum, marginibus fere ad 1/4 connatis; glabrum basi hyalinum, apice castaneum.

Nux parva (2,4-2,8 mm), oblonga, applanata in styli basin cylindricam subsensim abiens.

Stigmata 2 exserta basi breviter connata.

Typus:

China, Xinjiang, Central North Karakorum. "Nunatak" between K2-North Glacier and Skyang Kangri Glacier 4800 m. Dry alpine turf, dominant on margin of frost scree, with *Carex borii*. 1986-09-23. leg. *B.Dickoré 784* (**type**: **holo-** K, **iso-** PE).

Diagnosis

Differs from *K. pusilla* by the shorter perigyne which is connate at the base, the smaller nut which is 2.4-2.7 mm long (not 2.7-3.2 mm), and which is gradually tapering into the cylindric base of the style (not abruptly contracted), the androgynous partial spikes which contain 2 male (and one sterile) flowers (not 2-4 male flowers), the ovate glumes which are 2.5-3 mm long (not lanceolate, 3-4 mm) with a narrow (not broad) hyaline margin. Differs from *K. persica*, *K. humilis*, *K. royleana* by the two (not three) stigmas.

Description

Rhizome densely ramificating, woody, plants forming low cushions.

Culm (2) 3-15 (20) cm high, straight, rigid, subterete, striate, triquetrous above, smooth.

Leaves (usually) shorter than the culm, crowded, 1-2.5 mm broad, flat (to plicate), rigid, usually strongly recurved, basal sheaths brown, with (dead) leaf-blades.

Spike solitary, rarely compound, shortly cylindric, 5-12 mm long, 2-4 mm broad.

Partial androgynous spikes with 3-4 flowers, the basal one feminine, the upper two male (and one sterile).

Glumes ovate, 2.5-3 mm long, obtuse, brown, with a narrow hyaline margin.

Perigyne as long as the glume, elliptic, margin connate up to 1/4 of its length, glabrous, hyaline at base, castaneous above.

Nut small (2.4-2.8 mm), oblong, applanate, gradually tapering into the cylindric base of the style.

Stigmas 2, long exserted, at the base shortly connate.

D: ?E Pamir, Kongur, Wakhan, Chitral, Karakorum, Inner W Himalaya, Karakorum, NW Himalaya (Ladakh - W Nepal). *Endem.*

E: (3100-) 3800-5030 m, alp. - subniv., scattered, in high altitudes of the C. Karakorum locally common. High alpine turf on earthy, silty, usually slightly inclined permafrost slopes, up to the highest turf spots (*Carex borii, Stipa concinna, Potentilla pamirica*), often in contact with free gelifluction gravels (*Sibbaldia tetrandra, Saussurea gnaphalodes*); rarely below of the alpine belt in water-surplus habitats.

N: Except for the 2 stigmas and the somewhat narrower leaves sometimes difficult to distinguish from depauperate specimens of *K. royleana*. In the W Karakorum plants are found with variable stigma numbers (2-3, rarely 4), which might represent intermediates / hybrids with three-stigmatic species (*K. royleana, K. persica, K. humilis* ?). *K. karakorumensis* is to be expected in E Pamir, but obviously subject to some confusion with these species. The total distribution area and ecological requirements of *K. karakorumensis* apparently are very similar to those of *Carex borii*. Both are common in high altitudes in the western C. Karakorum and, apparently rather disjunct, also occur in SE Zanskar. *Kobresia royleana* (NEES) BOECK. var. *himalaica* RAJBHANDARI & H. OHBA, Univ. Tokyo Bull. **34**: 150, from Nepal, is possibly another segregate of *K. royleana*, which may also merit specific rank.

* **Kobresia kashgarica** DICKORÉ sp. nov. (§ *Elyna*)

Ic.: fig. 5 (1).

Diagnosis

Differt a *K. capillifolia* perigyniis basi ad tertiam partem connatis (nec subliberis) ab axe spiculae facile secedentis, nuce minore, 1,8-2,3 mm (nec 2,5-3,5 mm), spiculis partialibus androgynis flore masculo 1 (nec 2), glumis ovatis 2,5-3 mm longis (nec 3,5-5,5 mm) pallide viridi-cinnamomeis (nec atrofuscis), antheris 1-1,5 mm (nec 1,5-3 mm).

Descriptio

Rhizoma dense caespitosum.

Culmus (1) 2-5 (8) cm altus, gracilis, obtusangulus, laevis, ad basin vaginis efoliatis brunneis lucidis obtectus.

Folia culmum subaequantia, filiformia, convoluta, marginibus scabriuscula.

Spicula lineari-cylindrica, (5) 7-10 (15) mm longa, 2-2,5 mm lata.

Spiculae partiales laterales androgynae 2-florae (flos inferior femineus, superior masculus).

Glumae ovatae, 2,5-3 mm longae, pallide cinnamomeae, carina viridi.

Perigynium 2,2-2,6 mm, ovatum, subacutum basi ad tertiam partem connatum, hyalinum subter, pallide-brunnescens superne.

Nux parva (1,8-2,3 mm) obovata obtuse trigona breviter stipitata.

Stigmata 3.

Antherae 1-1,5 mm.

© Biologiezentrum Linz/Austria; download unter www.biologiezentrum.at

Typus:

China, Xinjiang, Kunlun Shan. Tiznap, tributary valley W of Kudi, 36°51'N/76°57'E, 4040 m. Alpine *Cyperaceae* mats (grazed loess slope with *Carex tangulashanensis*), 1992-07-09, *G. & S. Miehe 8471* (**type**: **holo-** K, **iso-** GOET, PE).

Diagnosis

Differs from *K. capillifolia* by the perigyne which is connate up to 1/3 (not almost free) and which is easily separating from the spike-axis (not difficult), the smaller nut which is 1.8-2.3 mm long (not 2.5-3.5 mm), the androgynous partial spikes which contain 1 male flower (not 2), the glumes which are 2.5-3 mm long (not 3.5-5.5 mm), ovate (not lanceolate), pale greenish-cinnamon coloured (not brown to black), the anthers which are 1.1.5 mm (not 1.5-3 mm) long.

Description

Rhizome densely caespitose.

Culm (1) 2-5 (8) high, delicate, subterete, glabrous, covered at the base by brown lucid, blade-less sheaths.

Leaves about the same length than the culm, filiform, convolute, margin scabrous.

Spike linear-cylindric, (5) 7-10 (15) mm long, 2-2.5 mm broad.

Lateral androgynous spikes 2-flowered (the lower flower feminine, the upper male).

Glumes ovate 2.5-3 mm long, pale cinnamon mith green midrib.

Perigynium 2.2-2.6 mm ovate, subacute, connate up to 1/3, hyaline below, pale brown above.

Nut small, 1.8-2.3 mm, obovate, obtuse trigonous in cross-section, shortly stipitate.

Stigmas 3.

Anthers 1-1.5 mm long.

A: W Kunlun: Tiznap Vy., W Kudi 4040-4340 m, *Miehe 8434!; 8471!.* ?Mazar P. N 4880 m, *Miehe 8365!* (young). **D**: W Kunlun, C.Tian Shan. **E**: (Kunlun:) 4040-4340 (-4880?) m, alp., loess covered, grazed slopes (*Kobresia capillifolia, Carex tangulashanensis*). **N**: Also found under very similar situations in the C. Tian Shan: Urumqi Vy., Shengli Daban 3700 m, *Miehe 9047!,* highest alpine turf (*Kobresia capillifolia, K. humilis, Carex tangulashanensis*). Probably a high alpine relict species of the mountains bordering to the Tarim basin, which may be expected in connecting localities; sympatric and perhaps intergrading with *K. capillifolia*. Although the chromosome numbers are unknown, it suggests a diploid (or lower level of polyploidy) in relation to *K. capillifolia*. The combination of the characters distinguishes *K. kashgarica* from previously described segregates, which seem to come much closer to *K. capillifolia*.

66. Kobresia macrantha BOECK., Cyper. Novae **1**: 39. 1888

Blysmocarex macrantha (BOECK.) IVANOVA 1939

Ic.: Fl.Xizang.5: fig.220. RAJBHANDARI & OHBA 1991: pl.68a, fig.7, fig.27.

CS **Nubra:** Nubra Vy., Liangtsung to Panamik [N 34°47' E 77°32'] (left side of the Nubra Vy.), 1856-07-24/31, *Schlagintweit* s.n. (KÜKENTHAL 1909, RAJBHANDARI & OHBA 1991; BM! [**?neotype**]).

Unloc.: Ladakh (HOOKER 1894; ? no specimen seen).

A: Himachal Pr.: Spiti, *Schlagintweit 1344* (BOECKELER 1888: **type** ? B destroyed). Baralacha P., *Bhattacharyya 40828* (BSD; ASWAL & MEHROTRA 1994).

D: Tibet (E Karakorum, SE Tibet), Inner Himalaya (Nepal, rare), W China (Gansu, Qinghai, Xizang, Sichuan). *Tibet.*

E: ? c. 3300 m, mont. - subalp., rare in the SE. Habitat in the Karakorum unknown. (Tibet:) alp., open dry to moderately moist turf on ± groundwater-influenced, loose (rhizome geophyte!) but stable substrates (moraines, fluvioglacial gravels); often as a pioneer.

N: A species of S Tibet, which enters the Karakorum from the E, the Nubra locality possibly being the westernmost outpost of its area. *K. macrantha* is very similar to *Carex pseudofoetida*, and perhaps closely related with the *Carex maritima* group, but differs in the open prophyll. Most easy, without causing destruction on herbarium specimens, *K. macrantha* is distinguished by the 3-4 mm long anthers, which are 2-2.5 mm in *C. pseudofoetida*. The records of HARTMANN (1966) are referable to *K. karakorumensis*, which is easily distinguished by the tufted habit and lacking stolons. *K. macrantha* is apparently erroneously reported from: Astor: *R.R.Stewart 18975* [= *Blysmus compressus* !]; **Gilgit:** *R.R.Stewart 26917* [= *Blysmus compressus* !]; Deosai: Marpo P., *R.R.Stewart 22274* [= *Kobresia royleana* !] (Ann.Cat.Pak.); *Meinertzhagen* s.n. [= *Carex pseudofoetida* + *Kobresia karakorumensis* !] Kashmir: Burzil P., *R.R.Stewart 19025* [= *Carex pseudofoetida*]. The following records are doubted although no herbarium material was seen: **Leh:** Himis, *Koelz 2557* (Ann.Cat.Pak.); **Nubra:** Siachen Gl., base camp 4850-4950 m, *Dainelli* (PAMPANINI 1934 [? perhaps *K. karakorumensis*].

[?]Rupshu: Tsokar, *Koelz 6600* (Ann.Cat.Pak.). W Tibet: Burang Vy., Nepal - Tibet border (N 30°09' E 81°18') 4400 m, *Miehe+9616d!.*

D: ?Wakhan, S Karakorum, W Himalaya (Hazara - W Nepal). *W Himal.*

E: (3050) 3950-4440 (4850) m, alp., locally common (SW). Closed turf, meadows and meadow-steppes, preferably under rather humid situations and with relatively long snow-cover; rarely in subalpine *Salix karelinii* scrub, flushes and high alpine free gelifluction slopes.

N: Specimens from the extreme W (Yasin) demonstrate a high variability of the culm length: 3-30 cm. The species is substituted by *K. robusta* on the Tibetan plateau, which appears to be closely related, but generally well separated. Hybrids and introgression between *K. nitens* and *K. schoenoides* may occur (?Wakhan, SW Tibet), but is not definitely verified. *K. burangensis* may represent a plant of *K. nitens* with unusually deeply split prophyll, or such a hybrid.

* **Kobresia persica** KÜKENTHAL & BORNM. 1897 - **A**: W & [?]E Pamir 2800-4300 m (Fl.Tadzh.). [?]Kashmir (Ann.Cat.Pak.) **D**: Turkey, Caucasus, Iran, Afgh., Pamir-Alai. **Map:** IVANOVA 1939: map 5. **N**: *Kobresia persica*: Persiae austro-orientalis, Prov. Kerman, Kuh-i-Lalesar 3800-4000 m, *Bornmüller 4800* (B! **type**) is at least poorly understood in the E part of its range. It may be synonym to *K. humilis*. Records from E Pamir (Fl.Tadzh.) may refer to *K. karakorumensis*, from Kashmir (Ann.Cat.Pak.) to *K. karakorumensis* or *K. royleana*.

* **Kobresia pusilla** IVANOVA 1939 - **Ic.: fig. 4** (2). **D**: C. & NE Tibet. **Map:** IVANOVA 1939: map 5. **N**: Plants which are ± intermediate between *K. pusilla* and *K. persica* are distinguished as *K. karakorumensis* (see there).

D: Tibet (W, C., N, E, S, SE to Kongbo); Inner Himalaya (Rupshu, Himachal Pradesh - Bhutan), W China (Gansu, Qinghai, Xizang, Sichuan, Yunnan). **Map:** IVANOVA 1939: map 5. *Tibet.*

E: 4980-5400 m, alp. - subniv., on turf in water-surplus habitats. The species has a very wide ecological amplitude in Tibet (see below).

N: The Ladakh record perhaps refers to the type locality on the SE extremity of Ladakh/Rupshu. The record from Deosai would represent a far western outpost and needs to be confirmed. It does not seem to be quite impossible regarding the Tibetan character of the Deosai Plains, but *K. pygmaea* is easily confused with depauperate specimens of other *Kobresia* species, as well as with small *Carex* species. *K. pygmaea* appears to be rather common, but ± restricted to water-surplus habitats on the E boundary of the area. This dwarf (only 1-2 cm high) species is the most common and characteristic plant of the Tibetan Plateau. It usually dominates often species-rich turf and forms a very hard sod which covers an immense area of the plateau (except for the driest parts), zonally between c. 4000 and 5300 m. The sods rather uniformly attain an average thickness of c. 15 cm (in C. Tibet / Tangula Shan, less in the dry areas of S and W Tibet) and apparently represent humus accumulation since the deglaciation of the Tibetan Plateau. Economically, *K. pygmaea* probably is the most important plant of Tibet, highly adapted and tolerant to grazing. Instead of its small size, it appears to be a main fodder-plant, and its distribution apparently coincides with the area of large-scale Yak-pasturing. The sods are used for building-purposes (walls, roofs, living erosion-control buildings). Under dry conditions, the *K. pygmaea* turf is more vulnerable to overgrazing and hardly regenerates after destruction by erosion or sod-plugging. Heavy grazing and large *Ochotona*-populations may cause a degradation towards dwarf nitrophilous weed-communities (*Microgynoeceun tibeticum*, *Microula tibetica*) or cushion-communities on deflation ground. Large areas in S Tibet (SW of Lhasa) apparently suffer from desertification and erosion following the destruction of the *K. pygmeaea* turf. "*Kobresia koelzii* KÜKENTHAL" (ined. ?): the "**type**" material is a mixture: Rupshu: Khyung Tso 5030 m, *Koelz 2246b* (K! = *Carex sagaensis* and *Carex microglochin*; W! = *Kobresia pygmaea* and *Carex microglochin*).

D: Dzung. Alatau, Tian Shan, Pamir-Alai, Kunlun, Karakorum, Afgh., Himalaya, Tibet (Qinghai, Xizang; W, N, C., NE, S, SE), Sichuan. **Map:** IVANOVA 1939: map 4 (*K. royleana, K. stenocarpa*). Pl.As.Centr. 3: map 4 (*K. stenocarpa*). *Centr.As.*

E: 2700-5100 m, (mont.-) subalp. - alp. (-subniv.), locally common. Usually in water-surplus habitats: flushes and fens (*Carex pseudofoetida*), among *K. schoenoides* tufts, riverside turf (*Blysmus compressus*) and scrub (*Salix pycnostachya, Carex orbicularis*), relatively rare zonally on high alpine turf (under relatively humid conditions / pass-situations, on loess, sedimentary rock-slopes). In Tibet a common component of water-saturated permafrost-bogs (*Kobresia pygmaea, K. schoenoides*).

N: A very protean species with a large altitudinal range. According to the ecological conditions, the height of flowering plants varies from c. 2 cm (high alpine turf) to 50 cm (montane sedge-flushes). The distinction of *K. stenocarpa* on account of nut characters does not seem to be practicable. The beak of the nut is of variable, but always evident length and easily breaks off together with the style and stigmas. From the spike-like inflorescences, the somewhat narrower leaves and the more fibrous dead leaf-sheaths *K. humilis* (Tian Shan populations) appears well set apart, but this and *K. royleana* may intergrade in the Pamirs. The two-stigmatic *K. karakorumensis*, which is always relatively dwarf, is a well-distinguished species, substituting *K. royleana* on high-alpine slopes in the central (granite) ranges of the Karakorum. Some records of *K. royleana* from the C. Karakorum, e.g. "abundant on `Green Island', upper arm of Ghondokoro Gl. at 16000-16500', here the commonest component of the vegetation but not seen at lower altitudes" (WEBSTER & NASIR 1965), may refer to *K. karakorumensis*, but not necessarily do so.

D: Caucasus, Armenia, Afgh., Pamir-Alai, Tian Shan, ?Altai, ?Siberia; Karakorum, Kashmir, Himalaya, Tibet, W China (Gansu, Qinghai, Xizang, Sichuan). **Map:** IVANOVA 1939: map 1 (*K. schoenoides, K. pamiroalaica, K. tibetica*). Pl.As.Centr.3: map 3 (*K. tibetica*). *Centr.As.*

E: (3450) 3700-4800 (5100) m, (subalp.) alp. (-subniv.), locally common. Meadow steppes of the S Karakorum; in the N Karakorum almost entirely confined to water-surplus habitats: flushes, fens, forming characteristic tufted naka-moors (with *K. royleana* often in the depressions); "flats along lateral moraine" (*Nasir & Webster 6182*), "growing in extremely tough tussocks 9" to a foot in diameter near wet ground" (*Osmaston 21*).

N: The thick, stout stems of *K. schoenoides* are very resistant against grazing and remain standing as dead stumps for years. The large and very hard tufts are a very characteristic component of Tibetan flushes. IVANOVA (1939) and EGOROVA (1983) considered *K. schoenoides* s.str. to be restricted to the Caucasus. *K. schoenoides* is extremely variable in the himalayo-tibetan area, but a very coherent complex, which apparently cannot be divided up. It includes very strong plants with broad

© Biologiezentrum Linz/Austria; download unter www.biologiezentrum.at

inflorescences as well as small Tibetan forms with narrow spikes. Undisturbed flowering plants growing under favourite conditions may have culms of up to 1 m, while dwarf forms are only 2-3 cm high. The variation appears to be largely dependent on climate conditions, growth-rhythm and grazing, without any clear taxonomic consequences. The inflorescence is apparently paniculate in well developed specimens, because of the high number of male flowers in the spikelets. Thus we consider *K. deasyi* and *K. pamiroalaica* extremes of an ecocline. *K. tibetica* MAXIM. (K! **isotype?**) apparently does not refer to the *K. schoenoides* group (*K. filifolia* ?). The identity of plants from NE Asia, Siberia and E Tibet is also dubious (*Kobresia smirnovii* IVANOVA, *Kobresia sibirica* TURCZ.). Few specimens are somewhat transitional between *K. schoenoides* and *K. nitens*. In Zanskar, where *K. nitens* occurs rarely, there may be intermediates, though hybridisation is not definitely proven. Wakhan specimens (KYO), referred tentatively to *K. nitens*, but differing in the open propyll, may represent a hybridogenous relict population.

* **Kobresia vidua** (C. B. CLARKE) KÜKENTHAL 1909 (*Carex vidua* BOOTT ex C. B. CLARKE in HOOKER f. 1894 - **A**: W Tibet: N Moincer (N 31°15' E 80°15') 5000 m, *Miehe+9644b!*. **D**: Inner Himalaya: Nepal, Sikkim; S & SE Tibet.

Putative hybrids:

There are morphological intermediates which may represent hybrids, such as **Kobresia laxa X K. royleana ?, Kobresia karakorumensis X K. royleana ?, Kobresia nitens X K. schoenoides ?**. There is, however, no indication to the nature of these plants since most *Kobresia* species are highly polymorphic.

D: Temp. Eurasia S to Pakistan: Punjab, Gilgit; Kashmir, N America; introduced in Australia, New Zealand, S America. *Holarct.*

E: 1800-3350 m, coll. - mont., not common in the SW (apparently rarer than *A. gigantea* in the Karakorum). *Artemisia* semi-deserts, scrub-steppes and open forest (*Juniperus excelsa, Pinus wallichiana*), on somewhat ruderal, eutrophic moist places. "It forms a close turf and is important in alpine pastures where it contributes significantly to the available fodder".

N: Difficult to distinguish from *A. gigantea*. The development of stolons (*A. stolonifera*) or rhizomes (*A. gigantea*) apparently is also depending on edaphical conditions. Provisionally, plants with an anther length of 1.0 - 1.2 mm are placed under *A. stolonifera*, those with anthers c. 1.5 mm long under *A. gigantea*, but the different levels of ploidy are said not to be distinctive. Both taxa grow on ± ruderal and water-surplus habitats, and there seems to be no clear cut chorological and ecological difference. Perhaps they are better regarded as subspecies. "*Agrostis* sp. = sp. H.f. & T. dist.", reported from Karakash Vy. 4570 m (HENDERSON & HUME 1873), probably belongs to another genus.

Bromus japonicus X B. pectinatus ?- The species have different levels of ploidy and are usually vicarious, but polymorphic and possibly hybridising in areas of contact.

Key to *Calamagrostis:*

1. Lemma not more than half as long as the glumes, hyaline, smooth. Callus hairs 2-3 times the length of the floret **2**

\+ Lemma at least two-thirds the length of the glumes, hyaline or firmly membranous, smooth or scaberulous. Callus hairs at most as long as the floret **4**

2. Awn subterminal, exceeding the tip of the lemma by 1.5-2.5 times the length of the floret ..... **(C. emodensis)**

\+ Awn subterminal or dorsal, exceeding the tip of the lemma by no more than the length of the floret .. **3**

3. Awn subterminal, arising from within 0.3 mm from the tip of the lemma ..... **C. pseudophragmites**

\+ Awn dorsal, arising from below the top third of the lemma, usually at about the middle, rarely below ..... **C. epigejos**

4. Panicle dense, ovoid to shortly lanceolate, 1.5-6 (-10) cm long, culms 10-40 cm high **5**

\+ Panicle usually lax, (8-) 10-25 cm long, culms 60-150 cm high **8**

5. Lemma blunt, ± sinuate (4 to many-tipped), awn distinctly geniculate in the free part. Panicle very congested, forming a compact ovoid head. Plant shortly rhizomatous, ± tufted **6**

\+ Lemma ± acute or 2-tipped, free part of the awn ± straight. Panicle usually not as compact. Plants usually with ± long creeping rhizomes **7**

6. Lemma c. $^{2}/_{3}$ the length of the glumes. Panicle shortly ovoid. Plants low, stout ..... **C. anthoxanthoides**

\+ Lemma c. $^{4}/_{5}$ the length of the glumes. Panicle shortly cylindric. Plants taller, ± lax..... **(C. laguroides)**

7. Glumes usually whitish hyaline. Lemma short, hyaline. Palea narrowly lanceolate, acute. Anthers short. Panicle usually dense, with relatively few spikelets. Surface of leaves usually with short soft hairs (SW Tibet, Himalaya) ..... **C. holciformis**

\+ Glumes dull grey-brown. Lemma longer, blackish at apex. Palea broadly lanceolate, 2-tipped. Anthers longer. Panicle dense to fairly lax, with many spikelets. Surface of leaves usually with short stiff spines (Tian Shan, Kunlun, N Karakorum, Pamir, Wakhan) ..... **C. tianschanica**

8. Awn arising from about the middle of the lemma or subterminal. Glumes usually deeply suffused with purple **9**

\+ Awn arising from near the base of the lemma. Glumes green, brown or ± tinged with purple **10**

W Tibet: Laptel to Seychell and Hoti (S of the Satlej), 1855-07-16/19, *Schlagintweit 7074* (GOET! ["*Avena subspicata* (var.) *pallida*" det. GRISEBACH]). In humidis altissimis Emodae Thibeta [NW Tibet, Bekar] 1831-08, *Jacquemont 1828* (K! **type**). Manasarovar Lakes, E Mapam Yumco, SE Hor (N 30°41' E 81°46') 4850 m, *Miehe+9594!*.

D: E Ladakh, NW & C. Himalaya (Zanskar - Nepal: Dhaulagiri region), SW Tibet. *S Tibet.*

E: 4100-4880 m, alp. - subniv., rare in the S & E. *Caragana* scrub, steppes, deserts, permafrost gravels, lake-shores.

N: The record from "Nubra" (HOOKER 1896) probably refers to the **Upper Shyok** locality. (Probably) in error reported from E Pamir: Tagdumbash Pamir, Pistan 4600 m, 1901-07-15, *Alexeenko* s.n. (Pl.As.Centr. "*C. compacta*" [? = *C. anthoxanthoides*]), Wakhan (PODLECH & ANDERS 1977 [*C. tianschanica*]) and N Karakorum (DICKORÉ 1991 [*C. tianschanica*]). Closely allied to and perhaps conspecific with *C. tianschanica*, which differs in the slightly smaller, usually not whitish florets, which usually are arranged in a higher number in a larger and more effuse panicle. The glumes of *C. holciformis* are either distinctly yellowish-white, variegated or dull brown, and also forms with rather effuse panicles occur. The rather long hairs on the leaf surface of *C. holciformis* (short stiff spines in *C. tianschanica*) are fairly distinctive. Reduced specimens of *C. holciformis* sometimes imitate *Trisetum spicatum* and are easily confused with this. *Calamagrostis przewalskyi* TZVELEV; 1968 from C. (E, SE) Tibet differs in the very dense globose heads and the long spines on glumes, pedicels and panicle branches.

* **Calamagrostis laguroides** REGEL 1881 (*Calamagrostis anthoxanthoides* (MUNRO) REGEL subsp. *laguroides* (REGEL) TZVELEV 1967, *Stilpnophleum laguroides* (REGEL) NEVSKI 1936) - **A**: W Pamir: common. E Pamir: Gorno-Badakhshan, W Pshart Vy. 3660 m, *Tzvelev 422* "*C. compacta*" (K!). **D**: Pamir-Alai. **N**: Similar to *C. anthoxanthoides* and replacing this in the W Pamir at relatively lower altitudes.

distinguish these taxa, and similarly reduced plants occur throughout the area of *C. pseudophragmites*. *C. dubia*, at least from the majority of Afghan specimens, belongs to (the typical subsp. of) *C. pseudophragmites*. The species is often misidentified as *C. emodensis*, and there remain some problems as to its proper morphological delimitation against *C. epigejos* and *C. stoliczkae*.

* **Calamagrostis pulchella** GRISEB. 1868 - **Ic.:** Fl.Xizang.5: fig.111. **A**: Zanskar: Pensi P. 4390 m, *Koelz 2928* (K!); 4330 m, *H.Hartmann 2547* (K!). Kargiakh 4150-4250 m, 1992-08-06; 1992-08-07, *Holzner & Kriechbaum* s.n.!. Kargiakh - Gombo 4200 m, 1992-08-08, *Holzner & Kriechbaum* s.n.!. Kashmir. Himachal Pr.: Lahul, via Kukti P. 4270 m, *Koelz 1214* (BM!). Marrhi 3630 m, 1992-08-16, *Holzner & Kriechbaum* s.n.!. Jispa, *Aswal 10647* (ASWAL & MEHROTRA 1994). W Tibet: Burang Vy., Nepal - Tibet border (N 30°09' E 81°16') 3800 m, *Miehe+9601a!;* 4400 m, *Miehe+9616b!*. **D**: Himalaya (Kashmir, Zanskar - Nepal). **N**: This apparenty was confused with *C. scabrescens*. The plants named cf. **Calamagrostis stoliczkae X C. arundinacea** (HARTMANN 1984: fig.9; pl.7) represent young, but fairly typical specimens of *C. pulchella*, which was previously collected in nearly the same locality by *Koelz*.

* **Calamagrostis scabrescens** GRISEB. 1868 (*Deyeuxia scabrescens* (GRISEB.) MUNRO ex DUTHIE in ATKINSON 1882) - **A**: Swat: Beyond Bishigram 3050-3350 m, *R.R.Stewart & A.Rahman 25010* (BM!, K!). Hazara: Kagan, 1899-07-26, *Inayat* s.n. (K!); Bhurji 3350 m, 1899-07-15, *Inayat* s.n. (K!). Kashmir: Sonamarg 2740 m, *R.R.Stewart 9815* (K!). Liddar Vy., Sonsal Nullah 3960-4270 m, *Duthie 13349* (K!). Pahlgam 3050-3350 m, *R.R.Stewart 21808a* (K!); Mts. opposite Pahlgam 3050-3350 m, *R.R.Stewart 21790* (K!). Himachal Pr.: Patseo, *Bor 15154* (DD; ASWAL & MEHROTRA 1994). **D**: Himalaya: Swat - Sikkim, ?SE Tibet. **N**: Excl. syn. *Calamagrostis filiformis* GRISEB. 1868 (*Deyeuxia filiformis* (GRISEB.) HOOKER f. 1896) which is another distinct species of the C.Himalaya. *C. scabrescens* is apparently confined to more humid situations than *C. pulchella*. Both species are frequently confused and they perhaps intergrade. A record of *C. scabrescens* from Leh: *Meebold* (STEWART 1916) may belong to *C. stoliczkae*.

Key to *Colpodium* and related taxa:

1. Plant with long creeping stolons and succulent stems, ± aquatic. Spikelets usually 2-flowered ..... *Catabrosa aquatica*
+ Plant densely tufted, without stolons, with or without short rhizomes, stems thin, usually in drier habitats. Spikelets 1-10 -flowered **2**
2. Midnerve of the lemma reaching right up to the obtuse or acute tip of the lemma. Lemma glabrous or with short diffuse hairs at the base. Spikelets (2-) 3-10-flowered ..... *Puccinellia*
+ Midnerve of the lemma not reaching the obtuse tip of the lemma. Lemma usually hairy at the base, with long hairs in distinct lines along the nerves. Spikelets 1-4-flowered **3**
3. Spikelets 7-10 mm long, 3-4-flowered; lemma 3.5-4.7 mm long. Panicle effuse, branches long and slender, ± flexuous. Plant rhizomatous ..... **(C. nutans)**
+ Spikelets 3-4.2 mm long, 1-2-flowered; lemma 2.5-4.2 mm long. Panicle ± contracted, with short rigid branches, often spike-like or with a few spreading branches. Rhizomatous or not **4**
4. Lower glume about 2/3, upper glume about 4/5 as long as the lemma. Lemma 5-6 mm long, with hairs 0.7-1 mm on the nerves below, whitish hyaline tinged with purple in upper part. Palea 5.5-6.5 mm. Spikelets 1-flowered. Anthers 2.5-3.5 mm long. Panicle ± contracted, 4-7 X 0.6-1.2 cm, often interrupted or with some longer, spreading branches. Plant robust, laxly tufted, shortly rhizomatous ..... **C. leucolepis**
+ Glumes 1/5 - 2/3 as long as the (lowest) lemma. Lemma 2.5-4.5 mm, with hairs 0.2-0.5 mm on the nerves below, dull greenish or golden-yellow hyaline ± tinged with purple in upper part above. Palea 3-4.5 mm. Spikelets 1-2 flowered. Anthers 1.5-3 mm long. Panicle usually highly contracted, narrowly or broader spike-like. Plants slender, densely tufted..... **5**
5. Spikelets usually 1-flowered. Glumes 1/5-1/3 the length of the lemma. Lemma greenish, hairy only well below of the middle. Anthers 1.5-2 mm long. Panicle narrowly spike-like, 2-4 X 0.2-0,5 cm ..... **C. himalaicum**
+. Spikelets 2-flowered, with the lower floret usually sterile. Glumes 1/2-2/3 the length of the (lower) lemma. Panicle broadly cylindric. Glumes, lemma and palea golden-yellow hyaline in upper parts. Lemma hairy on the nerves up to about the middle. Anthers 2-3 mm long. Panicle cylindric, 1.5-4 X 0.5-0.8 cm ..... **C. baltistanicum**

111. **Colpodium baltistanicum** DICKORÉ sp. nov.

Colpodium himalaicum auct. non (HOOKER f.) BOR 1960: WEBSTER & NASIR 1965, HARTMANN 1966, *Paracolpodium leucolepis* auct. non (NEVSKI) TZVELEV 1968: COPE 1980, ALEXEEV 1981 p.p.

Ic.: Fig. 6 (2), fig. 7 (1).

Species inter *C. leucolepidem* et *C. himalaicum* quasi intermedia.

Gramen perenne valde caespitosum sine rhizomatibus. Culmi fasciculati (5-) 7-15 (-20) cm alti, laeves, basi vaginis emortuis vestiti. Foliorum laminae lineares, plicatae, laeves glabraeque. Panicula densa, cylindrica, 1,5-4 X 0,5-0,8 cm, longe exserta, aurea. Spiculae 2-florae. Glumae subaequales, 2-3 mm longae. Lemma 3,5-4,5 mm longum elliptico-subacutum, praecipue ad nervos ciliatum ad mediam partem lemmatis. Paleae carinae ciliatae ad 3/4 longitudinem. Antherae 2-3 mm longae.

Habitat in graminosis cyperetis alpinis subhumidis (*Carex borii, Kobresia karakorumensis*) ad 3960 m usque ad 5030 m supra mare.

Typus: Karakorum, Biafo Gl., Baintha, NW-exponierte Felsrasen, 4500 m, 1962-07-23, *H.Hartmann 218* (**holotype** K!, **isotype** Z!).

way to Gilgit, *Sultanul Abedin & M.Qaiser 9146* (KUH). Kaghan Vy. Kashmir. Himachal Pr.: Khoksar, Aswal 6631 (ASWAL & MEHROTRA 1994).
D: Himalaya. *Sino-Him.* Species: *Euro-Sib.*
E: 3050-3350 m, montane, rare in the SW. Habitat not reported, probably on somewhat ruderal water-surplus habitats. (Generally:) meadows, "an excellent fodder grass" (Fl.Pak., for the species).

subsp. **woronowii** (OVCZ.) STEBBINS & ZOHARY 1959 (*Dactylis woronowii* OVCZ. 1934, *Dactylis glomerata* L. subsp. *hispanica* auct. non (ROTH) NYMAN 1882: BOR 1970) - Reported from Nuristan (PODLECH & ANDERS 1976).

N: The distribution of the subspecies of *Dactylis glomerata* in the Himalaya needs a (cytotaxonomic) reexamination with more material. Reported from Pakistan are subsp. **glomerata** (2n=28; throughout the range of the species) and subsp. **himalayensis** DOMIN (2n=14; Himalaya: Afgh. - Yünnan). **Dactylis glomerata** L. subsp. **hispanica** (ROTH) NYMAN (*Dactylis hispanica* ROTH 1797), (2n=28; Medit. - ?Afgh., ?Pakistan) may be substituted by subsp. **woronowii**. Subsp. **himalayensis** is considered "the commonest subsp. in the area; characterized by its looser fascicles of spikelets and shortly awned lemmas" (Fl.Pak.).*Stewart 26634*) has some long hairs on the lemma keels and may represent subsp. **glomerata**. Typical subsp. **himalayensis** seems to be a more easternly taxon, and the specimen from Gilgit (*Stewart 26634*) apparently represents subsp. **glomerata**. Lit.: DOMIN, Acta Bot. Bohem. 14 3-147. 1943.

* **Dactyloctenium aegyptium** (L.) WILLD. 1809 (*Cynosurus aegyptius* L. 1753) - **Ic.**: Fl.Iraq 9: pl.161. **A**: Hazara. Kashmir. **D**: Old world tropics.

119. **Danthonia cachemyriana** JAUB. & SPACH, Ill. Pl. Orient. **4**: 46, pl.331. 1851

Danthonia exilis HOOKER f. 1896, *Avena editissima* PAMPANINI 1915

Ic.: JAUBERT & SPACH 1851: pl.331.

CS **Shimshal:** Shimshal Gorge, Jurjur - Dut 2600-2730 m, *Miehe 5951!.* **Biafo:** Biafo Gl. W terminal moraine 3100 m, *H.Hartmann 79* (K!, RAW; HARTMANN 1966).

N **Upper Yarkand:** Camp Darva Serhot 4900 m, *Dainelli & Marinelli* (PAMPANINI 1930).

W **Gilgit:** Above Naltar 3200 m, 1954-07-23, *R.R.Stewart* s.n. (RAW). **Hunza:** Ulter Nullah 2740-3050 m, *R.R.Stewart 26633* (K!, RAW). **Batura:** W Khaibar (2500-3000 m), *Klötzli & al. 801.45* p.p.*!*.
A: [?] Nuristan. Dras: Matayan 30050-3350 m, *R.R.Stewart 7425* (KUH). Kashmir: 2440-3350 m. Near Gurais 2130-2440 m, *Duthie 12599* (K!); above Gurais 2440-2740 m, *Duthie 12591* (K!). Panicum crus-galli L. 1753

Ic.: Fl.Iraq 9: pl.185. Fl.Iran. 70: pl.67. Fl.Desert.Sin.1: fig.45(1-4: var. *mitis*).

S Skardu: 2440 m, 1940-08-05, *R.R.Stewart* s.n. (RAW). C. 1,5 miles E of Skardu 2290 m, *Nasir & Webster 6580* (K).

A: W Kashg.: Kashgar 1300 m, *Dickoré 998!*. Common about the city of Yarkand (HENDERSON & HUME 1873). Yecheng 1400 m, *Dickoré 125!*. S Kashg. (Pl.As.Centr.). Himachal Pr.: Keylong, *Bor (85186)*; rare (ASWAL & MEHROTRA 1994).

D: Warm temp. - subtrop. (-trop.) *Cosmopol.*

E: 2290-2440 m, coll., rare (S Karakorum). Ruderal, (seasonally) marshy places, irrigation canal sides, roadsides.

* **Echinochloa oryzoides** (ARD.) FRITSCH 1891 (*Panicum oryzoides* ARD. 1764) - **A**: N Kashg.; W Kashg.: Near Kashgar, 1929-07-26, *Popov*; S Kashg.: N Kunlun foothills, 1889-09-13, *Roborovsky* (Pl.As.Centr.). **D**: S Europe - E Asia.

* **Eleusine indica** (L.) GAERTNER 1788 (*Cynosurus indicus* L. 1753) - **A**: Kashmir. Hazara. **D**: Pantrop. - subtrop.

Elymus:

A difficult genus, well represented in the Karakorum. Hybridisation probably obscures the specific limits; several hybrids have been reported, but "none has yet been thoroughly investigated cytologically and experimentally to confirm its origin" (Fl.Pak.). The key and the species delimitation are mainly based upon Fl.Pak., which apparently works well in the Karakorum. Considerable difficulties to make this concept consistent to those of Pl.As.Centr. and Fl.Tadzh., do exist. Presently it seems to be impossible do evaluate many literature records relating to the flora of the Karakorum from these floras.

Key to *Elymus*:

1. Lemma awnless or with a short awn not as long as the body of the lemma 2
\+ Lemma with an awn at least as long as the body of the lemma 6
2. Plant loosely tufted, with long creeping rhizomes. Glumes acute, mucronate or shortly awned. Anthers 3.5-6 mm long. Leaves usually with long and short hairs above ..... **E. repens**
\+ Plant loosely to densely tufted, without rhizomes. Glumes obtuse, acute, acuminate, or toothed at the tip. Anthers 2-5 mm long. Leaves with short hairs above 3
3. Anthers 3-5 mm long. Glumes and lemma obtuse, quite smooth. Leaves narrowly involute ..... **E. cognatus**
\+ Anthers 2-2.5 mm long. Glumes and lemma acute, ± scaberulous or hairy. Leaves usually flat, broader 4
4. Body of the lemma with ± long hairs. Glumes toothed at the tip or acuminate ..... **E. dentatus**
\+ Body of the lemma smooth or scaberulous. Glumes acuminate 5
5. Lemma scaberulous all over the back ..... **E. mutabilis**
\+ Lemma smooth, the nerves thinly scabrid towards the tip ..... **E. stewartii**
6. Spikelets in groups of 2-3 in the middle part of the rhachis 7
\+ Spikelets solitary at all nodes of the rhachis (sometimes 2 spikelets together in *E. schrenkianus*) 8
7. Glumes almost as long as the lowest lemma (awns excluded) ..... **E. dahuricus**
\+ Glumes much shorter than the lowest lemma (awns excluded) ..... **E. nutans**
8. Awn of lemma straight or slightly flexuous 9
\+ Awn of lemma strongly recurved at maturity 12
9. Body of the lemma densely villous ..... **E. thomsonii**
\+ Body of the lemma scabrid or puberulous 10
10. Palea about three-quarters as long as the body of the lemma. Anthers 3-4 mm long .... **E. semicostatus**
\+ Palea about as long as the lemma. Anthers c. 2-3 mm 11

© Biologiezentrum Linz/Austria; download unter www.biologiezentrum.at

11. Lemma entirely glabrous or scabrid only near the tip ..... **E. caninus**
\+ Lemma minutely bristly or puberulous ..... **E. russellii**
12. Glumes almost as long as the lowest lemma (awns excluded) ..... **E. fedtschenkoi**
\+ Glumes considerably shorter than the lowest lemma (awns excluded) **13**
13. Rhachilla twisted above the glumes, midrib of lower glume not in line with that of the lowest lemma ..... **E. schrenkianus**
\+ Rhachilla not twisted above the glumes, midrib of lower glume in line with that of the lowest lemma **14**
14. Anthers (2.5-) 3-3.5 mm long ..... **E. canaliculatus**
\+ Anthers 1.5-2.5 mm long **15**
15. Leaves shortly and densely pubescent on both sides; flat or loosely rolled. Glumes short, obtuse, acute or ± emarginate ..... **E. schugnanicus**
\+ Leaves glabrous beneath, pubescent or loosely hairy above; flat, tightly folded or convolute. Glumes longer, acuminate or awned **16**
16. Glumes with an awn (2.5-) 4-10 mm long. Lemma body 11-12.5 mm long; scabrid or loosely villous. Leaves flat ..... **(E. himalayanus)**
\+ Glumes acuminate or with an awn up to 2 mm long. Lemma body 8-9 mm long; smooth or faintly scabrid. Leaves tightly folded, convolute or flat **17**
17. Leaves convolute or tightly folded. Body of the lemma smooth ..... **E. jacquemontii**
\+ Leaves flat to loosely convolute. Body of the lemma somewhat scabrid ..... **(E. tschimganicus)**

* **Elymus abolinii** (DROBOV) TZVELEV 1968 (*Agropyron abolinii* DROBOV 1925) - **N**: Possibly the hybrid *Elymus dentatus* X *E. gmelinii* (TZVELEV 1973).

D: Iran, Afgh., Pakistan (Chitral, Gilgit, Baltistan; Ladakh). *W Himal.*

E: 2350-3810 (4270) m, mont. - subalp., common in the W and S. A highly characteristic component of the *Artemisia brevifolia-Juniperus excelsa* forest-steppes of the lower subalpine belt, less common in *Juniperus sibirica* dwarf-scrub and in open *Pinus wallichiana* forests.

N: 2n = 14 (HUSS 1980, material from Wakhan). "According to BOR (1970) this is conspecific with *Agropyron ferganense* DROBOV 1916, but TZVELEV (1976) is not certain of this." (Fl.Pak.). *Agropyron cognatum* HACKEL var. *shingoense* MELDERIS was based on the same sheets (*Duthie 11895*) quoted by HACKEL as the type of *A. cognatum*, and is therefore invalid. These three type sheets, however, consist of specimens with ± shortly awned lemmas, which are not characteristic of the majority of the specimens of *E. cognatus* as understood later, but more of its putative hybrid with *E. repens*. *E. repens* is much rarer in the Karakorum, and most literature records of this, especially in the phytosociological literature (HARTMANN 1972, f.f.), probably belong to *E. cognatus*.

136. Elymus russellii (MELDERIS) T. A. COPE, Fl. Pakistan **143**: 618. 1982
Agropyron russellii MELDERIS in BOR 1960

CS **Biafo:** Biafo Gl. 4110 m, *R.Scott Russell 1800, 1809* (BM).

W **Yasin:** Naz Bar 3840 m, *Miehe 3348!* (sheaths subglabrous); 4100-4200 m, *Miehe 3462!; 3471!; 3575!; 3587!; 3588!*. **Hunza:** Rakaposhi N, above Nilt 3780 m, *Miehe 6526a!* (with *E. fedtschenkoi* and *E. mutabilis*). Above Chaprot 2500 m, *Schickhoff 168!*. **Hispar:** Hispar Gl. 3960 m, *R.Scott Russell 1553* (BM). Makerum, Hispar Gl. 3810 m, *R.Scott Russell 1388* (BM **type**).

D: W & S Karakorum. *Endem.*

E: (2500) 3810-4200 m, subalp.-alp., not common. Dry W-, S- & E-facing meadow steppes in the subalpine - alpine transition zone (Yasin), rarely reported from [rather dry ?] alpine turf (Hunza).

N: *E. russellii* probably arose from the hybrid *E. fedtschenkoi* X *E. mutabilis*. It grows under similar ecological conditions and often together with the putative parents. As regards the length of the arista and the indument of the sheaths (mostly only dense, very short retrorse hairs) it seems to be intermediate between and sometimes grading into one of the putative parent species. On the other hand, *E. russellii* probably merits specific recognition, since it may breed independently, probably developed a special ecological preference and distribution area, and has a characteristic habit.

D: C. Asia, Karakorum, Pakistan (Gilgit, Hazara), Kashmir, Himalaya. *Centr. As.*

E: (3620) 3850-5180 m, (subalp.-) alp. - subniv., frequent in N and C. Karakorum. Alpine turf, steppes (*Festuca olgae, Stipa purpurea*) and open scree slopes, up to the highest vegetation patches of the free gelifluction belt (*Sibbaldia tetrandra, Saussurea gnaphalodes*).

N: On the K2-N slope, *E. schrenkianus* probably reaches the highest altitude among the grasses. *E. schrenkianus* acts as the alpine vicariant of *E. nutans* which is mainly distributed in groudwater-influenced habitats of the subalpine belt. Some specimens of the subalpine-alpine transition zone are difficult to assign to one or the other species, when the characteristic twisting of the spikelet above of the glumes of *E. schrenkianus* is not clearly expressed. Reduced forms of *E. nutans* sometimes do not have more than one spikelet on the joints of the inflorescence. The indument of the lemmas is also variable; *E. schrenkianus* seems to have a tendency towards short, somewhat curved trichomes, while the lemmas of *E. nutans* mostly carry stiff spines. **Elymus schrenkianus** (FISCHER & MEYER) TZVELEV subsp. **pamiricus** (TZVELEV) TZVELEV, Nov. Syst. Pl. Vasc. 9: 62. 1972 (*Elymus pamiricus* TZVELEV 1960), **type** from E Pamir: W Pshart Vy.; also recorded from NW Tibet and Mongolia, is doubtfully distinct.

N: Very variable, the above cited material probably being not homogenous. Specimens determined as *E.* [*semicostatus* var.] *validus* are marked with an asterisk (*). This plant is very robust and resembles *E. fedtschenkoi* or *E. russellii*, it may merit specific recognition.

140. Elymus stewartii (MELDERIS) T. A. COPE, Fl. Pakistan **143**: 627. 1982

Agropyron stewartii MELDERIS in BOR 1960

W **Yasin:** Naz Bar 4100 m, *Miehe 3480!*. **Ishkoman:** Baru Gah 3450-3600 m, *Miehe 6779!*. Upper Baru Gah 3850 m, *Miehe 6863!*.

S **Leh:** N Leh 3650 m, *H.Hartmann 3014!*. **Lower Shyok:** Near Kasurmik, Shyok watershed 9-10000' [2740-3050 m], 1940-08-15, *R.R. & I.D.Stewart 20704* (K! **type**). Blaghar 3050 m, *R.R.Stewart 20844A* (K).

D: SW Karakorum (Gilgit, Baltistan). *Endem.*

E: 2740-4100 m, mont.-subalp., rare. *Juniperus sibirica* dwarf-scrub, tall forb communities in avalanche lines and meadow steppes.

N: *E. stewartii* probably arose from the hybrid between *E. mutabilis* and *E. repens*. The culms and sheaths of *E. stewartii* are glabrous and pruinose (*E. mutabilis*) but the leaf surfaces are sometimes covered with long and short hairs (*E. repens*). Regarding the ± stoloniferous to tufted habit, ± dense spikes, glumes which are spiny on the nerves and glabrous lemmas, *E. stewartii* is ± intermediate between the putative parents.

141. Elymus thomsonii (HOOKER f.) MELDERIS in HARA, STEARN & WILLIAMS, Enum. Fl. Pl. Nepal **1**: 132. 1978

Elymus thomsonii HOOKER f. 1896

CS **Shimshal:** Shachmirk P. W 4000-4200 m, *Miehe 6068!*.

N **Mustagh Ata:** SW 4000-4080 m, *Miehe 5895!*. **Taxkorgan:** Pirali - Taxkorgan 3800-3900 m, *Miehe 5230!*. S Taxkorgan, above Dafda 4110 m, *Miehe 5578!*. **Karakash:** SE Dahongliutan 4800-4850 m, *Miehe 7872!*.

W **Khunjerab:** P. SW 4150-4350 m, *Miehe 2530!*.

A: Kongur: Upper Oytag Vy. 3120 m, *Miehe 8671!*. W Kunlun: Tiznap Vy., W Kudi 3500-3700 m, *Miehe 8503!*. Himachal Pr.: Kunawur, above Lippa, 1847-08-20, *T.Thomson* s.n. (BM!). Uttar Pr.: Ganges Vy. below Rhudughara, 3050-3350 m, 1883-07-21, *Duthie* s.n. (BM!).

D: E Pamir, W Kunlun, N Karakorum; W Himalaya (Kunawur, Garhwal, Kumaon - Nepal). *Endem.*

E: 3800-4350 (-4850) m, subalp. - alp., rare / locally frequent in the NW. Steppes (*Festuca olgae*, *Artemisia compacta*, *Oxytropis* spp.), on open gravel and loess slopes, ± confined to the (lower) alpine belt and an altitudinal vicariant of *E. dentatus*.

N: The species is morphologically very distinct by its long awned, densely hairy lemmas, but hybrids are formed with very different species (*E. dahuricus, E. longe-aristatus*), probably also with the closely related *E. dentatus*. The distribution of *E. thomsonii* seems to be highly disjunct NW and SE of the Karakorum. There seems to be a considerable nomenclatural confusion around the species. "*Elymus thomsonii*" HOOKER f. in sched. (ined.?), is a different plant; a [?]**type** cover of this contains a sheet from Himachal Pr.: Piti, Dankar, 1847-09-02, *T.Thomson* s.n. (K!). This represents a strange, unidentified plant, actually inserted under *Leymus secalinus* (and perhaps a hybrid between this and another genus ?). *Agropyron alaicum* DROBOV 1916 (*Elytrigia alaica* (DROBOV) NEVSKI 1934) - **A**: Wakhan 3150 m, *Roemer 121* (M!; PODLECH & ANDERS 1977) and *Agropyron batalinii* (KRASN.) ROSHEV. 1915 (*Elytrigia batalinii* (KRASN.) NEVSKI 1934) - **A**: Wakhan 4000-4100 m, *Anders 7934* (M!; PODLECH & ANDERS 1977) probably belong here. **Elymus batalinii** (KRASN.) NEVSKI 1934 (*Triticum batalinii* KRASN. 1887, *Agropyron batalinii* (KRASN.) ROSHEV. 1915, *Elytrigia argentea* NEVSKI 1934) may be the correct name for the above taxon.

© Biologiezentrum Linz/Austria; download unter www.biologiezentrum.at

* **Elymus tschimganicus** (DROBOV) TZVELEV 1968 ("*Elymus czimganicus*", *Agropyron tschimganicum* DROBOV 1925, *Roegneria tschimganica* (DROBOV) NEVSKI 1934) - **A**: Kongur: Upper Oytag Vy. 3570-3900 m, *Miehe 8813; 9152!*. **D**: Dzungaria, Tian Shan, Alai, Kongu, ?E Pamir. **N**: Records of *A. tschimganicus* from **Mustagh Ata** (Pl.As.Centr.) and Wakhan (PODLECH & ANDERS 1977) probably belong to *A. jacquemontii*. Both species apparently have been mixed up occasionally. *E. tschimganicus* is a taller plant with ± flat leaves, and occurs in *Picea schrenkiana* forests of the N Tian Shan and the Kongur N slopes.

Possible Hybrids:

Elymus canaliculatus X E. cognatus (? *Elymus* X *incertus* H. HARTMANN 1984)
Ic.: HARTMANN 1984: fig.8; pl.6
W **Gilgit:** Above Phuparash 2860 m, *Schickhoff 783!*.
A: Zanskar: Doda Vy., S above Tungri 4000 m (HARTMANN 1984: **type** *E.* X *incertus*).
N: Rather *E. cognatus* than *E. repens* probably is the second parent of *E.* X *incertus*.

Elymus canaliculatus X E. fedtschenkoi ? (*Agropyron* X *interjacens* MELDERIS)
CS **Biafo:** Baintha 4150 m, *H.Hartmann 56!*.
W **Ishkoman:** Deux versants de l'Ishkoman Aghost 4210-4540 m, paturages et endroits humides, *F.Schmid 2430* (K! **type**).

Elymus canaliculatus X E. schrenkianus ?
W **Gilgit:** Baghrot Vy. 3830-3930 m, *Miehe 4243!; 4265!*.

Elymus canaliculatus X E. thomsonii ?
N **Taxkorgan:** S Taxkorgan, above Dafda 4110 m, *Miehe 5578!*.
N: ± intermediate between and growing together with its putative parents.

* **Elymus cognatus X E. nutans ?** (X *Agroelymus koelzii* MELDERIS) - **A**: Zanskar: Mune 12000'[3660 m], 1933-07-17/18, *Koelz 5741* (MICH **type**, foto !).

Elymus cognatus X E. repens ?
W **Gilgit:** Naltar Vy., Jagot 3100-33000 m, 1974-08-03, *F.Gartner* s.n. (GZU!). **Hunza:** Rakaposhi NW & W opposite Chalt 3360 m, *Miehe 5072!* (with *E. repens*: *Miehe 6697*). Minapin 2900 m, 1974-07-22, *F.Gartner* s.n. (GZU!).
S **Skardu:** Deosai N - Satpara 3760 m, *Miehe 5072!*.
N: Rather stout plants with flat leaves and with slightly spiny glumes and lemmas may represent this hybrid, which may be confused with *Elymus hispidus* (OPIZ) MELDERIS.

Elymus dahuricus X E. nutans ?
W **Batura:** Khaibar 2700-2760 m, *Klötzli & al. 118.03!; 801.72,108,112!*. E Morkhoon 3070 m, *Klötzli & al. 94.09!*.
N: ± intermediate and growing together with its putative parents by flushes of the lower subalpine belt.

Elymus dahuricus X E. thomsonii ?
W **Batura:** E Morkhoon 3590 m, *Klötzli & al. 89.18!*.
N: An incomplete specimen determined by Scholz as "*E.* cf. *dahuricus*", has the lemmas long ang densely hairy and long-awned as in *E. thomsonii*, but is a otherwise subglabrous plant like *E. dahuricus*.

Elymus dentatus X E. russellii ? (*Agropyron* X *spurium* MELDERIS)
S **Shigar:** Sokha Gl., right bank 4570 m, *R.Scott Russell 1627* (BM! **type**).

Festuca:

The genus, apparently, presents relatively few problems in the area. The species of the Karakorum usually are rather well defined, however, mostly on leaf anatomy. *Festuca* provides excellent geoecological monitor species with very characteristic distribution figures. For key and species descriptions see Fl.Pak. and ALEXEEV (1980).

Key to *Festuca* (adapted from Fl.Pak.):

1. Junction of leaf-blade and sheath auricled **2**
\+ Junction of leaf-blade and sheath not auricled **3**
2 Lemmas with an awn 10-18 mm long. Upper surface of leaves without ribs ..... **(F. gigantea)**
\+ Lemmas awnless or with a short awn up to 3 mm long. Upper surface of leaf-blade with prominent ribs. Auricles ciliate on the edge. Lower lemmas often awned ..... **(F. arundinacea)**
(Auricles glabrous. Lower lemmas awnless: **F. pratensis)**
3. Glumes entirely hyaline (except along the nerves), different in texture from the herbaceous lemmas .. **4**
\+ Glumes herbaceous, similar in texture to the lemmas **6**
4. Spikelets greenish-yellow ..... **F. karatavica**
\+ Spikelets whitish, tinged with purple or brown **5**
5. Leaf blades flat or loosely rolled. Ovary densely hairy at the tip. Plants dioecious ..... **F. olgae**
\+ Leaf blades folded. Ovary sparsely hairy at the tip. All spikelets bisexual ..... **F. alatavica**
6. Blades of all leaves flat, without ribs above. Ligule 3-8 mm long **7**
\+ Blades of leaves of vegetative shoots folded-setaceous, ribbed above. Ligule usually less than 1 mm long **8**
7. Lemma 5-nerved, 8-10 mm long ..... **(F. modesta)**
\+ Lemma 3-nerved, 5.5-7 mm long ..... **(F. asthenica)**
8. Lemma awnless or rarely with an awn-point or awn up to 0.8 mm long, glabrous **9**
\+ Lemma with an awn usually over 1 mm long, rarely awnless but then hairy **10**
9. Spikelets loosely disposed in an open panicle. Lemmas with a short awn-point or awn up to 0.8 mm long. Anthers 1.5-1.75 mm long (Kurram) ..... **(F. afghanica)**
\+ Spikelets densely crowded in a narrow panicle. Lemmas quite awnless. Anthers 0.8-1 mm long (Kashmir) ..... **(F. levingei)**
10. Leaf-blade scabrid on the lower (outer) surface for its whole length **11**
\+ Leaf-blade smooth on the lower surface or sometimes scabrid towards the tip **13**
11. Leaf-blade 6-sided in section with 7 approximately equal sclerenchyma strands ..... **F. kashmiriana**
\+ Leaf-blade flattened-cylindrical in section with 3 sclerenchyma strands, 1 on the keel and 2 marginal **12**
12. Leaf-blade 5-nerved, glaucous-pruinose ..... **F. valesiaca**
\+ Leaf-blade 7-nerved, usually green ..... **F. alaica**
13. Leaf-blade with 3 sclerenchyma strands, 1 on the keel and 2 marginal **14**
\+ Leaf-blade with 5-9(-11) sclerenchyma strands, these sometimes united into a continuous or interrupted cover **17**
14. Anthers 1.7-2.5 mm long. Sclerenchyma strands very prominent ..... **F. alaica**
\+ Anthers 0.7-1.4 mm long. Sclerenchyma strands usually less prominent **15**
15. Leaf-blade 5-nerved (rarely 7-nerved but then the outermost pair of nerves much smaller than the innermost pair) ..... **F. coelestis**
\+ Leaf-blade 7-nerved, the outermost pair being equal in size to the innermost pair **16**
16. Spikelets brown ..... **F. pamirica**
\+ Spikelets green, variegated with purple ..... **F. tibetica**
17. Anthers 0.5-0.8(-0.9) mm long ..... **F. nitidula**
\+ Anthers more than 1 mm long **18**
18. Leaf-blades flatted-cylindrical in section. Sclerenchyma in the form of a continuous or interrupted cover, in the latter case forming 3 broad strands or 5-7 narrower ones of which that on the keel is the most extensive ..... **F. hartmannii**

© Biologiezentrum Linz/Austria; download unter www.biologiezentrum.at

\+ Leaf-blades flattish or folded, in the latter case being angular and 4-many-sided in section. Sclerenchyma in (5-) 7-9 (-11) sparate strands of which that on the keel does not exceed any of the others in width **19**

19. Ovary densely hairy at the tip **20**

\+ Ovary glabrous or with just a few hairs at the tip (if rather more hairy then distinguished from *F. debilis* by the presence of sclerenchyma on the upper epidermis) ..... **F. rubra**

20. Leaf-blades of fertile culms flat. Spikelets 9-11 mm long. Anthers 1.7-2.2 mm long ..... **(F. debilis)**

\+ Leaf-blades of fertile culms folded-setaceous. Spikelets 14 -17 mm long. Anthers 2.5-3.5 mm long ..... **(F. simlensis)**

Uttar Pr.: Kumaon, Roghas up to the Milum Gl. to Bitterguar, 1855-06-18/19, *Schlagintweit* (LE; ALEXEEV 1980). Near Lebung P. *Duthie 6154* (LE; ALEXEEV 1980). W Tibet: Burang Vy., Nepal - Tibet border (N 30°09' E 81°18') 4000-4300 m, *Miehe+9629b!*.

D: SW Karakorum, W Himalaya (Swat - Kumaon). **Map:** ALEXEEV 1980: map 9. *W Himal.*

E: (2400) 2600-4580 m, subalp. - alp., common in the SW, rare in the C. Karakorum. Forests (*Picea smithiana, Pinus wallichiana, Betula jacquemontii*), relatively humid subalpine scrub (*Rhododendron anthopogon, Salix karelinii*) and alpine turf, up to the highest turf spots in the humid areas; more rarely in forest-steppes (*Juniperus excelsa, Artemisia* spp.), where in rock crevices, screes and other water-surplus habitats.

150. **Festuca karatavica** (BUNGE) B. FEDTSCH., Izv. Petersb. Bot. Sada 14, suppl. 2: 86. 1915

Poa karatavica BUNGE 1854, *Leucopoa karatavica* (BUNGE) V. KRECZ. & BOBROV in KOMAROV

W **Yasin:** Naz Bar 4330 m, *Miehe 3192!*.

A: Badakhshan: Anjuman P. E 4150 m. W Nuristan, Pirdum P. N (2300-3700 m), common, *G.Kerstan 1094* (W!).

D: W Tian Shan, W Pamir-Alai, Iran, C. & E Afgh. (Kabul, Parvan, Wardak, Bamian, Ghazni, Badakhshan, Nuristan), NW Pakistan (Yasin). *Ir.-Tur.*

E: 4330 m, alp., rare in the extreme W. Meadow steppe.

N: A large tufted grass, very common in C. Afgh.; avoided by grazing animals, probably because it is an aluminium-accumulator (BOR & MELDERIS in KÖIE & RECHINGER 1965). The locality of *F. karatavica* in **Yasin** is probably an isolated outpost of its distribution area. *F. karatavica* substitutes the C. Asiatic *F. olgae*; a similar case may be *Tricholepis toppinii* which in the extreme W Karakorum replaces *T. tibeticum*.

E: (2400) 3180-4630 (5180) m, subalp. - alp., locally common. Dry, but in the inner ranges usually N-facing, relatively stable scree and rocky slopes (granite, moraines), cliffs, steppes and scrub-steppes (*Juniperus turkestanica*, *J. sibirica*) and dry meadows. *Festuca olgae* forms a very characteristic and distinctive tussock-steppe belt on the subalpine-alpine border, especially in the N and C. ranges. "One of the most abundant and conspicuous grasses in the Upper Hushe Vy." (WEBSTER & NASIR 1965).

N: "*Colpodium afghanicum* BOR", from the type and only collection is a young and rather dwarf, but otherwise typical specimen of *Festuca olgae*. In the W (Afghanistan), *F. olgae* is substituted by *F. karatavica*; *Festuca nepalica* ALEXEEV 1977 is a closely related endemic of Nepal.

Trisetum litvinowii (DOMIN) NEVSKI subsp. *argentea* (GRISEB.) TZVELEV 1970 (non *Trisetum argenteum* (WILLD.) ROEMER & SCHULTES)

CS **Nubra:** Nubra, *Schlagintweit 2116* (M!). Tsarasa to Aranu (right side of the Nubra Vy., 1856-08-03/04, *Schlagintweit* s.n. (BM!). Panamik to Tsanglung (left side of the Nubra Vy.), 1856-08-09, *Schlagintweit 2239* (BM!).

S **Leh:** Leh, 1856-07-15/08-05, *Schlagintweit 951* (GOET! **holotype**; K! **isotype**). Indus Vy., Upshi - Leh (3660-4270 m), *F.Stoliczka* s.n. (K!). **Shyok:** [Calzar], 1848-07-22, *T.Thomson* s.n. (K!); 1848-07-23, *T.Thomson* s.n. (K!).

A: Wakhan: [?]3180-4900 m (PODLECH & ANDERS 1977, [localities and collection numbers partly the same as those cited under subsp. *litvinowii*, which is *Trisetum clarkei* !]). Kaharac 3000 m, *H.Roemer 381* (M!, W! [sub *K. cristata* det. BOR]). Zanskar: Kurgiakh 4150 m, 1992-08-07, *Holzner & Kriechbaum* s.n.!. [?] Himachal Pr..

D: Afgh. (Wakhan), ?Pakistan: Baluch.; E Ladakh, Inner Himalaya (Nepal), S & E Tibet, Kansu. "A rather rare species" (Fl.Pak.). *S Tibet.*

E: (3660-4270 m), subalp., rare in the E. Humid turf, moist open alluvial gravel by rivers and mountain streams.

N: A record from Baluchistan: Quetta hillside "only specimen from a front officer Quetta", 1956-05-07, *J.J.Norris 114* (K!), is doubtful regarding its identity and provenance. *K. argentea* occurs with certainty in the Wakhan, apparently very disjunct. The main area of distribution seems to comprise the interior dry valleys of S and E Tibet to Kansu. The distribution in the Upper Indus and Tsangpo valleys probably is not continuous, as are the localities in E Tibet separated by high mountain ridges. *K. argentea* and *K. litvinowii* are closely related and, although habitually different, there are no clear-cut differential characters separating them. They may merge one into another along the Kunlun Shan, but at present there is no evidence that they do so, and they probably are separated by a wide gap comprising the whole of the Karakorum range in the W. Both species are somewhat intermediate between *Koeleria* and *Trisetum*, intergeneric hybrid origin was suggested by TZVELEV in Pl.As.Centr.4. The putative parents probably are: *Koeleria cristata* X *Trisetum clarkei* = *Koeleria argentea*; *Koeleria cristata* X *Trisetum spicatum* = *Koeleria litvinowii*.

D: Trop. Africa, trop. & warm temp. Asia, Polynesia, N Australia. *Palaeotrop.*
E: 1520-2440 m, subtrop. - coll., rare in the SW.

Piptatherum:
A characteristic Irano-Turanian genus, with its species number quickly diminishing E of Wakhan and N of the Himalaya main range. No species has been reported from the Karakorum N slopes (except for one record of *P. gracile* close to the Shimshal P.) and Kashgaria so far. Species delimitation, synonymy and distribution features are mainly based on FREITAG (1975); see also for key; many specimens are actually determined by *Freitag*.

178. Piptatherum aequiglume (DUTHIE ex HOOKER f.) ROSHEV., Not. Syst. (Leningrad): 113. 1951
Oryzopsis aequiglumis DUTHIE ex HOOKER f. 1896, *Oryzopsis fasciculata* HACKEL 1902

Poa:

This is one of the most complex and difficult genera of the Karakorum. Numerous taxa have been described from adjacent areas. The species concepts of different floras are largely inconsistent. The genus is known for its intraspecific variation of chromosome numbers and high morphological plasticity. Numerous taxa are, apparently, poorly defined morphologically, although some of them may represent fairly stabilized and apomictic micro-species. Herbarium material, however, often is misidentified, and sometimes even not correctly allocated to species groups or sections. The most difficult group seems to be § *Stenopoa* (*P. nemoralis* group), which is distributed over all altitudinal belts of the whole mountain system and which includes some of the most common plants of the Karakorum (*Poa sterilis* and *Poa attenuata* or a number of ill-defined alpine taxa, *P. attenuata* group). The following treatment of this group is very provisional. Similarly problematic is § *Poa* (*P. pratensis* group), but here the intergrading complex is almost confined to the S Karakorum, whereas other related species seem to be fairly well defined. § *Bolbophorum* (*Poa bulbosa* group) apparently is absent from the C. Asiatic Karakorum N slope and entirely confined to the outer ranges of the S Karakorum. *Poa ladakhensis* H. HARTMANN 1984 proved to belong to *Puccinellia*.

Key to *Poa*:

1. Keels of palea with flexuous, curved or crispate hairs along almost the whole of their length. Annual or sometimes perennial (§ *Ochlopoa*) **2**
\+ Keels of palea scabrid or ciliate, if hairy then only in the lower half. Perennial, rarely annual **4**

© Biologiezentrum Linz/Austria; download unter www.biologiezentrum.at

2. Anthers (1.0) 1.3 - 2 mm long. Lemma elliptic, usually dark coloured towards the tip. Spikelets ± clustered towards the end of the panicle branches ..... **P. supina**
+ Anthers 0.6 - 0.8 (1.0) mm long. Lemma lanceolate, green or variously tinged with purple. Spikelets ± evenly spaced in the panicle **3**
3. Lemma without any wool at the base ..... **P. annua**
+ Lemma with copious wool at the base ..... **(P. nepalensis)**
4. Short living, vividly green or ± purplish tinged, flaccid perennials. Ligules long and acute. Lemma with copious callus wool. Palea keels spiny. Anthers 0.5 - 2 mm (§ *Coenopoa*) **5**
+ Perennials, usually long living, mid-green or glaucous, often more rigid. Ligules short and truncate or long and acute. Lemma with or without callus wool. Palea keels scabrid or ciliate. Anthers 0.5 - 3.5 mm **6**
5. Anthers 0.5 - 0.8 mm ..... **P. sikkimensis**
+ Anthers 1.5 - 2 mm ..... **(P. trivialis)**
6. Stem distinctly bulbous or thickened with the hardened or scarious remains of old leaf sheaths; plants densely tufted, not rhizomatous. Spikelets often viviparous, lemmas of the sexual spikelets broadly ovate (§ *Bolbophorum*) **7**
+ Base of stem not or only slightly bulbous. Rhizomatous or tufted plants. Plants rarely viviparous, lemmas lanceolate or sometimes ovate **9**
7. Base of stem enclosed into scarious remains of dead sheaths. Leaves broad, flaccid to ± coriaceous ..... **P. alpina**
+ Base of stem with a distinct hardened bulbous swelling. Leaves usually narrower, thin, ± ephemeric . **8**
8. Lemma (of sexual spikelets) with copious callus-wool and long hairs on the nerves below. Spikelets mostly viviparous ..... **P. bulbosa**
+ Lemma (of sexual spikelets) subglabrous, with only a few short hairs on the nerves below. Spikelets mostly sexual, sometimes viviparous ..... **P. bactriana**
9. Plants ± rhizomatous or loosely tufted with long or short ascending stolons, innovations extravaginal. Lemma with ± copious, sparse or rarely absent callus wool **10**
+ Plants densely tufted, without rhizomes or stolons, innovations usually intravaginal. Lemma without or with sparse callus wool (§ *Stenopoa*) **17**
10. Callus wool copious, consisting of a tuft of crispate hairs usually as long as or longer than the spikelet **11**
+ Callus wool absent, inconspicuous or consisting of a small tuft of crispate or ± straight hairs usually much shorter than the spikelet **13**
11. Lemma ovate, usually distinctly variegated with purple and with a broad yellow scarious margin. Keels of palea with very few short spines. Panicle effuse, panicle branches few, long and slender, the lower often reflexed, smooth or scabrid. Tiny plant (5-15 cm) with thin, long creeping rhizomes, high alpine ..... **P. calliopsis**
+ Lemma lanceolate, ± concolorous or usually less distinctly variegated, with narrow margin. Palea ± densely spiny on the keels. Panicle effuse to densly contracted, panicle branches usually many, rarely deflexed, scabrid or glabrous. Usually robust plants (15-50 cm) with thick rhizomes, various habitats **12**
12. Panicle highly contracted, spike-like with most branches not longer than the spikelets, smooth. Margin of lower glume often ciliate. Lemma lanceolate, pale-greenish. Stout and robust, very glaucous plant. Rhizomes long, thick (E Pamir, Ladakh, W Tibet) ..... **P. tibetica**
+ Panicle usually less contracted, most branches much longer than the spikelets, smooth or scabrid. Margin of lower glume smooth. Lemma lanceolate, green or variously tinged with purple. Plant slender, less robust, glaucous or green. Rhizomes short ascending or long, usually thin (S Karakorum, Himalaya and elsewhere) ..... **P. pratensis**
12a Pedicels and panicle branches smooth or very slightly scabrid, panicle usually contracted. Plants stout and rigid, with thick ± long rhizomes. Leaves tightly folded, usually short and rigid, very glaucous. Lemma ovate-lanceolate ..... **P. pratensis** subsp. **pruinosa**
12b Pedicels and panicle branches usually scabrid, panicle effuse to ± contracted. Plants ± slender and flaccid, with thin or short stolons. Leaves flat or folded, ± long ± flexuous, green to ± glaucous. Lemma lanceolate or lanceolate-ovate **12c**

© Biologiezentrum Linz/Austria; download unter www.biologiezentrum.at

12c Basal leaves tightly folded, 1-2 mm broad, usually mid-green, often nearly as long as the culms. Plants ± densely tufted, with short ascending stolons. Lemma ovate-lanceolate, 2-3 mm long ..... **P. pratensis** subsp. **angustifolia**

12d Basal leaves flat or loosely folded, 2-4 mm broad, green or glaucous. Lemma ovate to lanceolate, 2-5 mm long **12e**

12e Plants usually 15-70 cm, culms and leaves flaccid to ± robust. Panicle branches variously scabrid. Lemma greenish or variously tinged with purple, with ± distinct scarious margins ..... **P. pratensis** subsp. **pratensis**

12f Plants 5-15 cm, stout and rigid. Panicle branches densely scabrid with short spines. Lemma variegated, deeply suffused with purple and with prominent scarious margins ..... (**P. pratensis** subsp. **staintonii**)

13. Plant loosely tufted **14**

\+ Plant densely tufted **18**

14. Anthers small 1.8 - 2.5 mm ..... (**P. pagophila**)

\+ Anthers 2.5 - 3.5 mm **15**

15. Stout, rigid, glaucous plants ..... **P. lipskyi**

\+ Slender and lax plants, usually not glaucous **16**

16. Lemma entirely glabrous ..... **P. suruana**

\+ Lemma densely hairy below **17**

17. Lemma 5-nerved, hairy in the lower third. Sheaths and leaf-blades smooth ..... (**P. falconeri**)

\+ Lemma 7-nerved, hairy on the faces up to about the middle. Sheaths and leaf blades scabrid ..... **P. gilgitica**

18. All culm nodes usually included into leaf-sheaths, leaves almost all basal. Panicle ± contracted with relatively few and large spikelets, these usually variegated with purple. Glumes ovate to lanceolate. Lemma variously hairy or glabrous between the nerves. Plants (2-) 5-20 (-50) cm, ± dwarf or stout, growing on alpine to subnival turf and screes ..... **P. attenuata**

\+ Culm usually well exserted from the leaf-sheaths, with distinct, often black nodes visible at least in the basal part, with leaves usually up to the middle or higher. Panicle effuse to ± contracted, with relatively small spikelets. Spikelets usually ± concolorous greenish, sometimes suffused with purple. Glumes ± lanceolate. Lemma usually glabrous between the nerves, with long hairs on lateral nerves. Plants (10-) 20-50 (-80) cm high, ± slender, growing in colline to subalpine steppes, meadows and forests **19**

19. Ligule 0.5 - 0.8 mm. Glumes very unequal, the lower one-nerved, narrowly lanceolate with green midrib and broad scarious margin. Usually green, slender and flaccid plants. Panicle usually effuse (in full flowering), panicle branches slender. Anthers 1.2-1.5 mm. Rare in the SW Karakorum, in moist shady places of the colline and lower montane belt ..... **P. nemoralis**

\+ Ligule 1 - 3 (-5) mm. Glumes subequal or ± unequal, 3-nerved. Usually glaucous, ± stout or rigid plants. Panicle usually ± contracted, with few, short rigid branches. Anthers 1.4-2.0 mm. Common in the W & S Karakorum, dry to moderately moist colline to subalpine steppes, meadows and forests ..... **P. sterilis**

E: 3340-4890 m, alp., locally common in the S & W Karakorum. Moist alpine turf with long snow cover (*Kobresia nitens, Carex stenocarpa*), in "snow-valleys" and subalpine scrub (*Betula utilis, Salix karelinii, Rhododendron anthopogon*), rare and confined to meadow steppes of the subalpine-alpine transition zone in the arid regions.

© Biologiezentrum Linz/Austria; download unter www.biologiezentrum.at

N: Usually a very distinct species in the area, though vegetatively plastic. Nevertheless, *P. alpina* has been confused and mixed up with various other species (e.g. *P. calliopsis*, *P. pratensis*, *P. supina*) in literature records, which obscures the northern and eastern limits of its distribution. The species is frequently viviparous in Europe, but apparently always sexual in Central Asia.

E: c. 3000-3500 m, mont., rare. Cultivated and ruderal moist open places, perhaps undercollected. "A common weedy species found in a variety of habitats. 1400-4300 m." (Fl.Pak.).

* **Poa araratica** TRAUTV. 1873 (*Poa versicolor* BESSER subsp. *araratica* (TRAUTV.) TZVELEV 1974). - **D**: Turkey - Turkmenistan. **N**: Specimens often assigned to this are fairly frequent in the mont. - subalp. (alp.) belt of the SW Karakorum on meadows, relatively humid meadow steppes, rocks, in scrub and forest (*Salix karelinii*, *Betula jacquemontii*, *Juniperus turkestanica*). "Very similar to *P. sterilis*, but has a short, thick rhizome and the uppermost node is near the base of the culm. It is also rather similar to *P. attenuata*, but has longer spikelets and lemmas." (Fl.Pak.). The specimens are more or less intermediate between *P. sterilis* (subalp.) and *P. attenuata* (alp.) and are perhaps of hybridogenous origin. The *Poa attenuata* - *P. sterilis* complex appears to be almost continuous, but whereas the extremes are usually quite distinct, the intermediates do not seem to deserve specific status. They are highly variable, but probably best placed under the respective ill-defined species or regarded as transitional forms.

D: Central Asia: Siberia, Altai, Mongolia, Tian Shan, Pamir-Alai, Kunlun, Karakorum, Himalaya, Tibet. *Centr.As.*. **Map**: RAJBHANDARI 1991: fig.33 (*P. lahulensis*).

E: (3350) 3930-5300 m, alp.-subniv., common. Dry alpine turf (*Kobresia capillifolia*), steppe (*Oxytropis densa, O. chiliophylla, Stipa purpurea, St. subsessiliflora, Festuca olgae*) and semi-desert, screes slopes, rock-fissures, permafrost gravel.

N: *Poa attenuata* is one of the most common components of the alpine flora of Pamir, Karakorum and the Tibetan Plateau. It is close to and perhaps conspecific with the circumarctic-alpine **Poa glauca** VAHL, Fl. Danica **6** (17): 3. 1790. The *Poa attenuata* group is highly polymorphic and represents one of the most problematic complexes in the flora of High Asia. Much more work has to be done to reexamine its variation. Numerous taxa have been described (more recently CUI & CUI 1987). Some of them may represent discrete (apomictic ?) populations, but their morphological characters are often very indistinct and certainly highly plastic. The indumentum of the spikelets, often employed for distinguishing *P. lahulensis* (lemma hairy between nerves), *P. koelzii* (callus-wool), and other micro-species does not seem to be a reliable character and is often variable in one panicle. The delimitation of the alpine *P. attenuata* group against the montane-subalpine *P. sterilis* group (*P. nemoralis, P. sterilis*) presents further problems. However, the over-all variation does not seem to be quite

© Biologiezentrum Linz/Austria; download unter www.biologiezentrum.at

continuous, but there are many specimens, mainly from middle altitudes and often assigned to *P. araratica* (*P. versicolor* subsp. *araratica*), see there, which seem to be more or less intermediate between what is here called *P. attenata* and *P. sterilis*. There is no positive (morphological or ecological) indication that these intermediates, which are also extremely variable, do represent another distinct species, nor about the identity of the C. Asiatic plants and *P. araratica*.

A: Chilas: Gor 3230 m, *Schickhoff 1520!.*

D: SW Karakorum, Indus Gorge: Upper Chilas, Gilgit, Lower Hunza, W Baltistan. *Endem.*

E: 2910-3600 m, mont.-subalp., rare in the SW Karakorum. Moist shady, usually N-facing *Picea smithiana* forests, somewhat ruderal (grazing places), more rarely in *Pinus wallichiana*, *Betula jacquemontii* forest and *Juniperus* scrub.

N: This seems to be, like *Poa suruana*, another local derivate of the *P. falconeri* group; *P. stapfiana* is apparently also closely related. *P. gilgitica* is characterized by its very scabrous leaf-blades and sheaths, and 7-nerved pubescent lemmas. It appears to be ecologically isolated and ± confined to *Picea smithiana* (and potential *Abies webbiana* ?) forests of the Indus Gorge (see *Allium gilgiticum*, *Carex oligocarya*).

* **Poa glabriflora** ROSHEV. 1936 (*Poa bactriana* ROSHEV. subsp. *glabriflora* (ROSHEV. ex OVCZ.) TZVELEV 1973 - **A**: Zanskar: Chumik Marpo 4800 m, 1992-08-04, *Holzner & Kriechbaum* s.n.!. Sarchu 4400 m, 1993-07-23, *Holzner & Kriechbaum* s.n.!. **D**: Pamir, Hindukush, W Himalaya (insuffiently known).

* **Poa himalayensis** NEES ex STEUDEL 1854 - **A**: Kashmir. Himachal Pr.: Rohtang P. 3600 m, 1992-08-17, *Holzner & Kriechbaum* s.n.!. **D**: Himalaya (Kashmir - Bhutan), SE Tibet, Assam.

189. Poa lipskyi ROSHEV., Bull. Jard. Bot. Pétersb. **30**: 303. 1932

Poa dschungarica ROSHEV. 1932, *Poa taldyksuensis* ROSHEV. 1950 (diagn.ross.), *Poa kungeica* GOLOSK. 1955, *Poa litwinowiana* auct. non OVCZ. 1933: DICKORÉ 1991

A: W Kunlun: Akaz P. 3260-3300 m, *Miehe 7377!; 7421!.* Mazar P. NE 4380 m, *Dickoré 285!.* E Pamir.

D: Dzung. Alatau, Tian Shan, Pamir-Alai, W Kunlun, N Karakorum. *E Pamir.*

E: 4110-4420 m, (subalp.-) alp., rare in the NW. Steppes (*Festuca olgae*), turf, tall forb communities (*Carex nivalis, Delphinium brunonianum*) on stabilized moraine gravels; *Caragana*- scrub. Apparently more common and characteristic on alpine loess slopes of the Kunlun Shan.

N: **Type** from Dzung. Alatau (LE). The plants from **Mintake** (*Caragana* scrub) are relatively large and less glaucous. They may represent a separated population somewhat transitional to *P. pratensis* subsp. *pruinosa*, which grows in the same locality. *Poa hissarica* ROSHEV. 1941 (? *Poa laudanensis* ROSHEV. 1934) is close to *P. lipskyi*, but has a subglabrous lemma.

190. Poa nemoralis L., Sp. Pl. 69. 1753

W **Ghizar:** Gupis 1980 m, *Bowes Lyon 8031* (K!). Kargah Vy. 2500 m, *Bowes Lyon 8021* (K!). **Hunza:** Pisan 3100 m, *G.Braun 558!; 561!.*

D: Temp. Eurasia, S to Pakistan: Baluch., Punjab, NWFP, Gilgit; Kashmir, Ladakh. *Euro-Sib.* Species: *Holarct.*

E: (2880-) 3150-4350 (-4440) m, subalp., common in the SW. Various mesophytic and semi-arid habitats: forests and scrub (*Pinus, Juniperus, Betula, Salix*), meadows and dry alpine turf. With its creeping rhizomes, *Poa pratensis* prefers stable, but not too hard soils on moraines or fine gravel, where it also occurs as a pioneer; not in bedrock fissures and hard, saline alluvial soils. "A very common species of old meadows and pastures where it affords excellent grazing and makes good hay." (Fl.Pak.).

N: Specimens marked with an asterisk (*) are reported as *P. angustifolia*, but may refer to the typical subsp. Specimens from rather high altitudes around Leh (*Caragana versicolor* dwarf scrub) and possibly other localities, marked (**), somewhat approach *P. calliopsis*. They may represent results of hybridization and introgression, but further studies are needed.

D: Tian Shan, Pamir-Alai, S Karakorum, W Himalaya. *?E Pamir.*

E: 3170-4150 m, subalp. - alp., scattered. Open alluvial sands, by glaciers, alpine turf and free gelifuction gravel with relatively long snow cover.

N: This, under the name *P. tianschanica* (which probably is a synonym of *P. tibetica*), has been considered of hybrid origin of *P. pratensis* X *P. tibetica* by TZVELEV 1976. It is somewhat intermediate between them and fills the gap between Pamir and Tibet, where *P. tibetica* apparently is absent today. It is usually distinct by the characters given in the key, but apparently freely grading into subsp. *pratensis* and perhaps subsp. *angustifolia* as well. *Poa tibetica* seems to be set off a little better, while there apparently are also hybrids between *P. pratensis* subsp. *pruinosa* and *P. lipskyi*. The Central Asiatic plant seems to be reasonably different from the circumarctic **Poa pratensis** L. subsp. **alpigena** (BLYTT) HIIT. 1933 (*Poa pratensis* L. var. *alpigena* BLYTT 1861). *Poa bucharica* ROSHEV. 1923 from W Pamir and *Poa jaunsarensis* BOR 1948 from C. Himalaya apparently are also closely related.

E: 2630-4400 m, mont. - subalp., common in the SW. *Artemisia brevifolia-Juniperus excelsa* steppe-forest, *Juniperus communis* dwarf scrub.

N: One of the most common plants of the montane and subalpine belts of the W & S Karakorum. Specimens ± intermediate between *P. sterilis* and *P. attenuata* are apparently rather common in the subalpine - alpine transition belt of the SW Karakorum, e.g. **Gilgit** between (3600) 4000-4200 m. Some of these putative hybrids, which were often named *Poa versicolor* subsp. *araratica,* are marked with an asterisk (*), but they are so variable as compared to the typical species on both ends of the range of morphological variation (*P. sterilis*, *P. attenuata*), that it seems to be impossible to keep them for a distinct species. The specimen *H.Hartmann 188* from **Biafo** is cited as *P. nemoralis* (Fl.Pak.), but it is a rather robust plant with ligule 0.8 - 1.3 mm and thus resembles more *P. sterilis;* it may represent a hybrid.

* **Poa stewartiana** BOR 1951 - **A**: Swat: Beyond Bishigram 3660 m, *R.R.Stewart 25642* (K!). Hazara. Kashmir: Gulmarg, 3050 m, *R.R.Stewart 8675* (K!). **D**: NW Himalaya.

N: 2n = 28 (HUSS 1980, material from Wakhan).

Puccinellia

"The genus is badly in need of a major revision. Many of the species are represented only by a handful of specimens (some only by the type) so their full range of variation cannot yet be established." (Fl.Pak.). The Karakorum belongs to the C. Asiatic centre of variation of this exceedingly difficult genus. The number of species reported from the Karakorum and adjacent areas, however, seems to be too high. Since a thorough revision should include much more herbarium material and a cytological investigation, only a superficial treatment or a selected enumeration of taxa and some of their probable interrelations can be given here (see also under *Colpodium*). The polymorphism of *Puccinellia* probably is, at least in part, due to hybridisation and resulting polyploidy and aneuploidy, which produces very variable chromosome numbers, similar to those known from *Poa*. The ecology of *Puccinellia* species in C. Asia also presents interesting problems. There are widely-distributed

© Biologiezentrum Linz/Austria; download unter www.biologiezentrum.at

halophytes (*P. distans*), as well as apparently highly isolated species confined to singular (hot) springs (*P. thomsonii*). Others are high alpines, one of them probably reaching the highest altitude among the grasses of W Tibet (*P. himalaica*: 5490 m).

Key to *Puccinellia*:

1. Anthers 1.7 - 3 mm **7**
+ Anthers 0.4 - 1.4 mm **2**
2. Lemma hairy at the base **3**
+ Lemma entirely glabrous **5**
3. Anthers 0.4 - 0.7 mm; usually large, rather lax plants of saline places at lower altitudes ..... **P. distans**
+ Anthers 0.7 - 0.9 mm; low, rather rigid, densely tufted plants of high altitudes **4**
4. Panicle effuse, panicle branches long, capillary, scabrid. Leaves glaucous, tightly convolute, c. 0.5 mm in diameter ..... **P. hackeliana**
+ Panicle contracted, panicle branches short, stout, glabrous or slightly scabrid. Leaves green, flat or laxly convolute (then c. 0.8 mm in diameter) ..... **P. humilis**
5. Panicle contracted, with few spikelets, branches mostly simple, glabrous. Leaves fresh green, soft, usually much shorter than the culms. Plants low ..... **P. minuta**
+ Panicle usually effuse (in full flowering), with many spikelets, branches often furcate, glabrous or scabrid. Leaves ± greyish green or glaucous, rigid, reaching up to half of the culm length. Plants often taller **6**
6. Palea keels smooth. Panicle branches usually smooth. Anthers 0.5 - 1.2 mm. Small plants of the upper alpine belt ..... **P. himalaica**
+ Palea keels scabrid. Panicle branches usually scabrid. Anthers 0.9-1.4 mm. Usually robust subalpine plants ..... **P. tenuiflora**
7. Panicle contracted, branches short, mostly simple, smooth. Leaves fresh green, smooth. Plant low, (2-) 5-15 (-20) cm ..... **(P. subspicata)**
+ Panicle branches and pedicels scabrid, panicle effuse, with long ± furcate branches. Leaves scabrid above. Plants robust (15-) 20-50 (-60) cm **8**
8. Lemma obtuse or rounded at the tip ..... **(P. stapfiana)**
+ Lemma acute at the tip ..... **P. thomsonii**

* **Puccinellia akbaitalensis** OVCZ. & CZUK. 1957 - **A**: Reported from Wakhan (PODLECH & ANDERS 1977); probably *P. pamirica* (see there).

198. Puccinellia distans (JACQ.) PARL., Fl. Ital. 1: 367. 1848

Poa distans JACQ. 1764, *Glyceria distans* (JACQ.) WAHLENB. 1820, *Atropis distans* (JACQ.) GRISEB. in LEDEB. 1852

Ic.: Fl.Desert.Sin.1: fig.20(9-13).

W **Ishkoman:** Imit (rivulet) 2400 m, 1974-08-10, *F.Gartner* s.n. (GZU!). **Batura:** Borit Jil 2500 m, *F.A.Perrot 11* (K!).

S **Shigar:** Karakorum 3260 m [Shigar - Skoro P.], 1876-08-07, *C.B.Clarke 30133* (K!). **Leh:** [Wandla - Kalatze 3170-3350 m], 1848-07-07, *T.Thomson* s.n. (K!). Leh 3500 m, 1992, *Holzner & Kriechbaum* s.n.!.

Unloc.: Balti, *Schlagintweit 5898!* (GOET!).

Yarkand 1350 m, 1930-03-18, *Persson 85a* (PERSSON 1938: *P. glauca*). W Kunlun: Tiznap Vy., Kudi 3000-3050 m, *Dickoré 182!* (partly viviparous); *226!*. E Pamir. Wakhan: ? Near Yamit 2800 m, *Roemer 270* (M!).

D: Temp. Eurasia, N Africa; N America. *Holarct.*

E: 2500-3260 (3500) m, coll. - mont., rare. Wet or irrigated saline habitats: "small saline lake, pH 8.9, in marshy ground at edge of lake" (*Perrot 11*); (Kunlun:) flushes, river gravel, by irrigation canals.

© Biologiezentrum Linz/Austria; download unter www.biologiezentrum.at

N: Probably represented in the Karakorum by **Puccinellia distans** (JACQ.) PARL. subsp. **distans**; the differential characters of subsp. **glauca** (REGEL) TZVELEV 1976 (*Glyceria distans* (JACQ.) WAHLENB. var. *glauca* REGEL 1881, *Atropis glauca* (REGEL) V. KRECZ. 1934, *Puccinellia glauca* (REGEL) V. KRECZ. ex PERSSON 1938) from C. Asia and Pakistan (Baluchistan) are rather vague. Variable chromosome numbers (2n = 14, 18, 19, 24, 32, 34, 36, 42), counted by *A. Dieterle* in 1968, are marked on a voucher specimen cultivated from *Roemer 270*, the single specimen of *P. distans* seen by me from Wakhan. Since it is morphologically not quite definite, it may be a hybrid (with *P. pamirica* ?). Most of the material cited by PODLECH & ANDERS 1977 (from higher altitudes) apparently belongs to *P. pamirica*. The specimen *Holzner & Kriechbaum* s.n. is very small in all its parts and has only a few hairs at lemma base, untypical and perhaps a recent and casual introduction in Ladakh (hotel surroundings).

subsp. **sevangensis** (GROSSH.) TZVELEV 1976 (*Puccinellia sevangensis* GROSSH. 1928) - **A**: Wakhan: Deh Ghulaman 3000 m, *Roemer 321*; Sarhad 3180 m, *Anders 7167* (M!); (PODLECH & ANDERS 1977). **D**: Caucasus, ? SW Asia. **N**: Poorly understood and perhaps best regarded as a subspecies of *P. distans*. The specimen seen from Wakhan (*Anders 7167*) apparently comes close to subsp. *distans*. The Afghan material determined as *P. sevangensis* (in M!) is not necessarily identical with the Caucasian plant and apparently very heterogenous as well.

199. Puccinellia hackeliana (V. KRECZ.) V. KRECZ. ex PERSSON, Bot. Not. **1938**: 275. 1938

Atropis hackeliana V. KRECZ. 1934

Changtang: Guliya Ice Cap (N 35°12' E 81°31') 5490 m, *L.G.Thompson* (GOET!). Tibet, Dali (N 35°18' E 87°35') 4950 m, *Wellby & Malcolm* s.n. (K!).

D: W (? & C.) Tibet, Kunlun, N & E Karakorum, E Ladakh, Lahul. *Tibet.*

E: (3650-) 4620-4900 (-5300) m, alp. - subniv., not common (N & E Karakorum). Permafrost, usually water surplus habitats (glacier run-off, lake shores), up to the highest turf spots (*Kobresia schoenoides, K. royleana, Carex sagaensis*), often eutrophic (animal resting places) gravels and sands. Reported to ascend to the highest altitude (> 5500 m) among the grasses in adjacent NW Tibet.

N: The material cited (cf.) from Karakash and Aksai Chin is very young, with only remains of inflorescences of the previous year. It might well belong here, but other species may also be involved in the very high altitudes of Tibet. The delimitation of *P. himalaica* against *P. tenuiflora*, though a plant of much lower altitudes, seems to be problematic, since the characters (anther length, spines on palea keels and panicle branches) grade into another.

201. **Puccinellia humilis** (V. KRECZ.) ROSHEV., Fl. Kirgiz. 2: 140. 1950

Stipa:

Monographed by FREITAG (1985); see for synonyms, key, descriptions and distribution maps; many specimens determined by Freitag. *Timouria* and *Trikeraia* are retained as separate genera here.

Synopsis (FREITAG 1985)

Sect. *Achnatheropsis* TZVELEV: *St. brandisii*, *St. regeliana*
Sect. *Barbatae* JUNGE emend. FREITAG: (*St. arabica*)
Sect. *Lasiagrostis* (LINK) HACKEL: (*St. caragana*), (*St. chitralensis*), *St. jacquemontii*, *St. splendens*
Sect. *Pseudoptilagrostis* TZVELEV: *St. subsessiliflora*
Sect. *Ptilagrostis* (GRISEB.) HACKEL: *St. concinna*, *St. mongholica*
Sect. *Stipa*: *St. breviflora*, *St. capillata*, *St. caucasica*, *St. himalaica*, *St. koelzii*, *St. orientalis*, *St. pennata*, *St. purpurea*, (*St. roborovskyi*), *St. turkestanica*

Key to *Stipa* (adapted from FREITAG 1985):

1. Awn 7-40 mm long **2**
\+ Awn longer than 40 mm **14**
2. Awn plumose throughout, with the hairs at the base at least 1 mm long **3**
\+ Awn scabrous throughout, or only the lower part plumose or pilose **5**
3. Awn longer than 30 mm ..... **(St. roborovskyi)**
\+ Awn shorter **4**
4. Panicle spike-like, contracted ..... **St. concinna**
\+ Panicle loose, with spreading, flexuous branches ..... **St. mongholica**
5. Awn in lower part plumose or pilose, with hairs of at least 0.4mm **6**
\+ Awn scabrous throughout **8**
6. Awn in lower part plumose, hairs at its base 2-3 mm long ..... **St. subsessiliflora**
\+ Awn in lower part pilose, hairs at its base 0.4-1 mm long **7**
7. Callus up to 0.5 mm long, rounded. Lemma membranous, with 0.5-1mm long apical lobes. Hairs at the base of the awn c. 0.5 mm long ..... **(St. duthiei)**
\+ Callus 0.7-1 mm long, acute. Lemma coriaceous, without apical lobes. Hairs at the base of the awn c. 1 mm long ..... **(St. regeliana)**
8. Awn bigeniculate. Lemma dark brown, coriaceous ..... **St. brandisii**
\+ Awn straight or variously geniculate, if geniculate or flexuose or flexuose, the lemma never brown and coriaceous **9**
9. Awn almost straight. Mature lemma chartaceous, with 2-6 deflexed spinules of 1-2 mm at the apex. Panicle contracted ..... **(St. roylei)**
\+ Awn geniculate or flexuose, twisted in lower part. Mature lemma membranous, without deflexed spinules. Panicle effuse or contracted **10**
10. Lemma with prominent apical lobes of 2-3 mm **11**
\+ Lemma lobes only up to 1 mm long **12**

11. Lemma lobes awn-like, setaceous. Awn 8-14 mm long. Glumes 7.5-9.5 mm long ..... **(Trikeraia)**
\+ Lemma lobes plane, membraneous. Awn 18-21 mm long. Glumes 9.5-12 mm long .. **(St. chitralensis)**
12. Panicle contracted, up to 2 cm wide. Awn 20-35 mm long ..... **St. jacquemontii**
\+ Panicle more effuse, at least 4 cm wide. Awn 5-14 mm long **13**
13. Tufts small; culms slender. Glumes subequal. Apical lemma lobes 0.2-0.4 mm long ..... **St. caragana**
\+ Tufts large to very large; culms stout. Glumes unequal, the lower 1-2 mm shorter. Apical lemma lobes 0.5-1 mm long ..... **St. splendens**
14. Awn scabrous throughout ..... **St. capillata**
\+ Awn pilose or plumose throughout or in parts **15**

© Biologiezentrum Linz/Austria; download unter www.biologiezentrum.at

15. Awn pilose with hairs up to 0.9 mm only in its lower part, upper part scabrous ..... **St. koelzii**
\+ Awn pilose or plumose throughout, or in upper part only, with longer hairs **16**
16. Awn pilose or plumose throughout **17**
\+ Awn pilose or plumose only in upper part, at least the segment below the first geniculation glabrous **24**
17. Awn pilose, with hairs 0.6-2.5 mm long **18**
\+ Awn plumose, with hairs 4-11 mm long **21**
18. Awn (8-)10-15(-22) cm long. Glumes (22-)25-35(-40) mm long..... **(St. arabica)**
\+ Awn 5-7 cm long. Glumes 12-17 mm long **19**
19. Awn with hairs of 0.6-1(-1.2) mm. Lemma spinulose-scabrid towards the top and with a crown of stiff hairs at the tip..... **St. breviflora**
\+ Awn at least in lower part with longer hairs. Lemma without a crown **20**
20. Panicle contracted, many-spiculate. Anthecium 6.5-7.5 mm. Awn in lower part with longer hairs (1.5 mm) than in the upper (1-1.1 mm) ..... **(St. roborovskyi)**
\+ Panicle usually loose, few-spiculate. Anthecium 8-9.5 mm. Awn in lower part with shorter hairs (1-1.5 mm) than in the upper (2mm) ..... **St. purpurea**
21. Awn unigeniculate ..... **St. caucasica**
21a Hairs below geniculation of awn 1.5-3 mm long. Usually tall, robust plants ..... **St. caucasica** subsp. **caucasica**
21b Hairs below geniculation of awn 1.0-1.5 mm long. Usually low, gracile plants ..... **St. caucasica** subsp. **glareosa**
\+ Awn bigeniculate **22**
22. Anthecium at least 15 mm long. Awn longer than 17 cm ..... **St. pennata** (aberrant forms)
\+ Anthecium 6-11.5 mm long. Awn up to 14 cm long **23**
23. Anthecium 6-9.5 mm long. Awn up to 7 cm long, falcate; hairs below first geniculation c. 1 mm long. Leaf sheaths and dead blades usually pale brown to grey ..... **St. orientalis**
\+ Anthecium 9.5-11.5 mm long. Awn 7.5-14 cm, flexuose; hairs below first geniculation c. 3 mm long. Leaf sheaths and dead blades usually yellowish-brown to bright yellow-orange..... **St. himalaica**
24. Anthecium 6-8 mm long. Awn 6-8 cm long ..... **St. tianschanica**
\+ Anthecium 9-26 mm long. Awn 8-45 cm long **25**
25. Awn 8-16(-19) cm long. Anthecium 9-12.5(-14) mm ..... **St. turkestanica**
\+ Awn (17-)25-38(-45) cm long. Anthecium (15-)17-23(-26) mm ..... **St. pennata**

214. **Stipa arabica** TRIN. & RUPR., Sp. Gram. Stip. 77. 1842

Stipa orientalis TRIN. in LEDEB. var. *persica* TRIN. 1830, *Stipa szovitsiana* (TRIN. & RUPR.) GRISEB. in LEDEB. 1852, *Stipa barbata* auct. non DESF. 1798: BOR 1970 p.p.

Ic.: Fl.Iraq 9: pl.150.

W **?Ishkoman:** Upper Ishkoman, Baru Gah 3050-3130 m, *Miehe 6762!* (cf., veg.). **Hunza:** Rakaposhi N, above Nilt 2450 m, *Miehe 6392!*.

A: W Pamir: Vakhan, pr. Vrang 3120 m, *Ovczinnikov & Afanassiev 1735* (LE **type** *St. pamirica* ROSHEV.); Wakhan: Qala-e-Ust - Baba-e-Tangi 2850 m, *Anders 7075* (*Stipa arabica* TRIN. & RUPR. var. *pamirica* (ROSHEV.) FREITAG 1985); Sar-i Shkhaur 2700 m, *Roemer 35* (PODLECH & ANDERS 1977). Chitral: 2300-3300 (var. *arabica*; FREITAG 1985). Chitral 1830 m, *Harriss 16783* (BM!).

D: S Sinai, Turkey, Caucasus - Iran, Afgh., W Pakistan, W Pamir, Tian Shan. **Map:** FREITAG 1985: fig.25. *Ir.-Tur.*

E: 2450 (-?3130) m, mont., rare in the W. *Artemisia brevifolia-Juniperus excelsa* forest-steppes.

N: A very characteristic Irano-Turanian element. Plants from the extreme E of its distribution area are distinguished as **Stipa arabica** TRIN. & RUPR. subsp. **pamirica** (ROSHEV.) FREITAG 1985 (*Stipa pamirica* ROSHEV. 1949, *Stipa badachschanica* ROSHEV. subsp. *pamirica* (ROSHEV.) TZVELEV 1974). The records of *Stipa barbata* DESF. 1798, from **Leh:** Himis Shukpa; Leh (STEWART 1916) probably are erroneous and may belong to *St. himalaica* or *St. pennata* subsp. *kirghisorum*.

* **Tragus roxburghii** PANIGRAHI 1974 (*Tragus biflorus* SCHULTES 1824 excl. typo) - **A**: Swat. Hazara. Kashmir. **D**: E Africa; Pakistan - SE Asia.

* **Trikeraia hookeri** (STAPF) BOR 1955 (*Stipa hookeri* STAPF 1895, *Timouria aurita* HITCHCOCK 1933) - **Ic.**: Fl.Xizang.5: fig.140(1-7). **A**: Rupshu: Kugzil 4270 m, 1931-07-16, *Koelz 2328* (K! **type** *Timouria aurita*). W Tibet: E Wuma (N 32°34' E 83°22') 4650-4660 m, *Miehe+9680f!*. **D**: S Tibet (Rupshu/Upper Indus - Lhasa/ Upper Tsangpo), Inner Himalaya (Nepal, Sikkim, ?Bhutan). **N**: Reported in error from Chitral, which was the type of *Stipa chitralensis* (FREITAG 1985). A record from **Nubra**, *T.Thomson* (HOOKER 1896) is doubtful: no specimen seen, perhaps *Stipa splendens*. The type locality probably is in the vicinity of Lhasa: Tibet, sheltered nullahs 14800' [4510 m], 1891-07/09, *W.G.Thorold 124* (K! **type**). The genus *Trikeraia*, which was included into *Stipa* sect. *Lasiagrostis* by FREITAG (1985) is retained here in spite of the somewhat intermediate position of *Stipa chitralensis*. A second species of *Trikeraia*, **T. oreophila**, was described meanwhile. Both species differ from *Stipa* by the awn-like, elongated nerves of the lateral lemma-lobes (hyaline lobes in *Stipa chitralensis* and *Stipa splendens*) and show some (superficial ?) resemblance to *Calamagrostis*-species. **Trikeraia pappiformis** (KENG) P. C. KUO & S. L. LU 1987 (*Stipa pappiformis* KENG) - **Ic.**: Fl.Xizang.5: fig.140(8-12), reported from Tibet 3400-3500 m, might represent a third species.

* **Trikeraia oreophila** COPE 1987 - **A**: W Tibet: N Moincer (N 31°15' E 80°15') 5000 m, *Miehe+9644e!;* 5050-5280 m, *Miehe+9642c!*. **D**: S & SE Tibet, Inner C. Himalaya (Nepal - Bhutan).

* **Tripogon purpurascens** DUTHIE 1901 - **A**: Swat. Hazara: Kaghan Vy. Kashmir. **D**: W Himalaya: Swat - Nepal.

Trisetum s.l.:

The perennial species of *Trisetum* (*T. spicatum* group) are imperfectly understood and apparently intergrading. They are also difficult to distinguish from species of *Koeleria* with short, ± straight awns (*K. argentea, K. litvinowii*), which probably are results of intergeneric crosses. Small specimens of *Calamagrostis holciformis* and *C. tianschanica* are often confused with *T. spicatum* (s.l.), but they lack the wooly indument of the inflorescence axis and branches.

Key to *Trisetaria* and *Trisetum*:

1. Annual ..... **Trisetaria loeflingiana**
\+ Perennial (*Trisetum* s.str.) **2**
2. Culm glabrous below of inflorescence. Leaves subglabrous ..... (**T. aeneum**)
\+ Culm ± densely hairy below of inflorescence. Leaves variously pubescent or ciliate **3**
3. Inflorescence a long, narrow, ± interrupted panicle. Culm usually > 50 cm. Leaves densely hairy with very long hairs or glabrescent except for long ciliae along the leaf-margin ..... **T. clarkei**
\+ Panicle very congested, dense, shortly cylindric. Culm usually less than 30 (-50) cm. Upper surface of leaves with persistent indument of short hairs or densely long hairy or subglabrous, leaf-margin with short or only basally a few long ciliae ..... **T. spicatum**
3a Leaves with short persistent hairs or glabrescent ..... **T. spicatum** subsp. **himalaicum**
3b Leaves densely covered with persistent long hairs ..... (**T. spicatum** subsp. **tibeticum**)

Changtang: Lungmu Co 5280 m, *Miehe 8163!*. **D**: S, W & C. & SE Tibet. **N**: The plants from very high altitudes in Zanskar, W Tibet and Changtang are very distinctive in having a very dense indument of short hairs on the leaves, but they apparently intergrade with subsp. *himalaicum*, which often has subglabrous leaf-surfaces.

Trisetum aeneum X T. clarkei ?

W **Gilgit:** Baghrot Vy. 3470 m, *Miehe 4029!;* 3800 m, *Miehe 3891* (K!); above Gutumi Nullah 3040 m, *Schickhoff 569!*. **Hunza:** Rakaposhi N above Nilt 3470 m, *Miehe 6428!*. Above Nilt, Masot Gl. 3170-3210 m, *Schickhoff 216!; 257!*.

E: 3040-3800 m, mont.-subalp., rare in the SW. Humid forests (*Picea smithiana, Pinus wallichiana, Betula jacquemontii*) and scrub (*Salix karelinii, Rhododendron anthopogon*).

N: Plants ± intermediate between their putative parents. None of the Karakorum plants seems to represent typical *T. aeneum*. They have the culms subglabrous above, branches and axis of panicle ± pubescent, the leaves ± densely ciliate. They grow together with *T. clarkei*. Typical *T. aeneum* has characteristically shining brown glumes, strongly reflexed awns, and is almost totally glabrous.

Trisetum clarkei X T. spicatum ?

W **Gilgit:** Shinghai Gah - Pahot Gali 4180-4280 m, *Miehe 995!; 1202!; 1237!; 1558!; 1591!*: *T. clarkei* > *T. spicatum*; 3950-4470 m, *Miehe 989!; 1059!; 1253!; 1660!; 1670!*: *T. spicatum* > *T. clarkei*.

A: Hazara: Kaghan Vy., Babusar P.: 3940-4310 m, *Miehe 280!; 318!; 348!; 484!; 509; 527!; Schickhoff 90/955!; 90/975!*.

E: 3950-4470 m. Humid alpine turf of the lower alpine belt.

N: Specimens cited are a purely accidental selection of possible intermediates.

Gagea:

The present stage of examination and species delimitation in the area appears to be more or less a chaos, no consistent revision is available. The number of recorded species appears far too high. The genus certainly exhibits a high degree of variation in the Irano-Turanian region (W Pamir-Alai), but the number of species quickly diminishes towards the East. Realistically, 5-8 species are to be expected for Kashmir, around 4 for the Karakorum, and only one species (*G. elegans*) appears to be distributed throughout the Himalaya. At present can be given only a highly speculative combined list of the various taxa recorded from the Karakorum and adjacent areas, and occasional herbarium material.

CS **Biafo:** Cho Blok 4180-4250 m (HARTMANN 1966); 4250 m, *H.Hartmann 331!*; *337* (Z!); 3900 m, *E.Reiser* (Z!). **?Saltoro:** Ghondokoro Gl. 4270 m, *Nasir & Webster 6019* (WEBSTER & NASIR 1965: "*G. gageoides*"). **Nubra:** Siachen Gl., base camp 4750-4800 m, 1930-07-19, *Dainelli* (PAMPANINI 1934, **type**).

W **Khunjerab:** Dhee Sar Vy., 4150-4420 m, *Ebenhöh* s.n. (M!).

S **Leh:** Tirdik, upper Bedashisa Vy., near Sabu 4900 m, *Billiet & Leonard 6866* (K!).

Unloc.: Nubra and Shaksgam Vy., *Clifford 46* (Ann.Cat.Pak.: *G. persica*); Sutyalik 4360 m, *Clifford 46* (K!).

D: S & W Karakorum. *Endem.*

E: 3900-4900 m, alp., scattered. Relatively humid alpine turf; "locally common on grassy banks" (WEBSTER & NASIR 1965).

N: A doubtful and poorly understood species.

* **Gagea jaeschkei** PASCHER 1904 (*Gagea pamirica* GROSSH. 1935) - **A**: Reported from E Pamir: Ucha, 1909-06-17, *Divnogorskaya* (Pl.As.Centr.). Wakhan 4200 m (PODLECH & ANDERS 1977). Asankitchal 4600 m, *Breckle 1362* (Fl.Iran). **D**: NE Afgh., Pamir-Alai, Himalaya: Chitral - Himachal Pr. **N**: Perhaps only a form of *G. elegans*.

* **Gagea kashmirensis** TURILL 1928 - **A**: Kashmir 1520-1830 m. **D**: Endemic. **N**: Of doubtful status.

* **Gagea lowariensis** PASCHER 1910 - **A**: Chitral: Madaklasht 2440 m, *Bowes Lyon 625* (BM!). Lowari P. 2740 m, *Stainton 2331* (BM!). Bundai 2830 m, *Harriss 16698* (BM!). Swat: E Kalam 3000 m, *Lamond 1833* (Fl.Iran.). Hazara (Ann.Cat.Pak.). **D**: E Afgh., NW Pakistan. **N**: RECHINGER in Fl.Iran. considers it a well marked species. R.R.STEWART's view "This is probably only a vigorous form of the common *G. elegans*" (Ann.Cat.Pak.) is perhaps more appropriate.

* **Gagea olgae** REGEL 1865 - **A**: Wakhan: Baroghil 3810 m, *Bowes Lyon 1006* (BM!). Chitral: Owir (Nichagh) 3510 m, *Bowes Lyon 876* (BM!); *Bowes Lyon 887* (BM!). Birmogh Lasht (N 35°55' E 71°46') 3350 m, *Bowes Lyon 733* (BM!). Turikho Rv., Istar 3200 m, *Stainton 2495* (BM!). **D**: Iran, Afgh., W Pamir-Alai, NW Pakistan. **Gagea setifolia** BAKER 1881 (see there) and **Gagea chomotuwae** PASCHER 1907 are closely related.

* **Gagea pseudoreticulata** VVED. 1932 - Reported from **Hunza:** Chalt (Ann.Cat.Pak.); doubtful. **A**: W Pamir 400-2400 m (Fl.Tadzh.). **D**: W Tian Shan, W Pamir-Alai, Afgh.

254. **Gagea setifolia** BAKER, J. Linn. Soc., Bot. 18: 101. 1881

Gagea aitchisoniana A. TERR. 1904

W **Gilgit:** Haramosh 2740 m, 1928, *F.Ludlow 251* (BM!).

A: W Pamir, E Pamir 2300-3400 m (Fl.Tadzh.). Chitral: Owir 3350 m, *Bowes Lyon 873* (BM!); 3810 m, *Bowes Lyon 881* (BM!). Khot An N Mastuj 3960 m, *Stainton 2847* (BM!). Astor: Harchu Vy., left slope above Lathang, 3480 m, *Nüsser 863!;* right slope above Baro-Nirril3230 m, *Nüsser 875!.* Deosai: Deosai 3300-3600 m, 1991-07-12, *Poelt* s.n.!.

D: S Iran, Afgh., Pamir-Alai, NW Pakistan (Kurram, Chitral, SW Karakorum). *Ir.-Tur.*

E: 2740 m, mont., rare in the SW. Habitat unknown.

* **Gagea vvedenskyi** GROSSH. 1935 - **A**: W Pamir, E Pamir 900-3600 m (Fl.Tadzh.). **D**: Tian Shan, Pamir-Alai.

D: Circumarctic - alp., S to Caucasus, Pamir, Hindukush, Himalaya, Japan. *Holarct.*

E: (3000) 3510-4850 m, alp., common in the SW, rare or absent in the NE. Alpine turf, meadow-steppes, among rocks, on open screes.

N: Variable; some plants from the Karakorum S slope are very robust (some N American as well). Since there seems to be no clear altitudinal/ecological separation inside the Karakorum population, regarded as belonging all to *L. serotina*. The genus, however, is polymorphic in the Himalaya. A key is given in Enum.Pl.Nepal and, recently, in Fl.Bhutan. The leaves of *L. serotina* (and other species of *Lloydia* ?) are collected as a Tibetan drug (*Kennedy 15*).

* **Notholirion thomsonianum** (ROYLE) STAPF 1934 (*Fritillaria thomsonianum* ROYLE 1839, *Lilium roseum* WALL. ex HOOKER f. 1853) - **A**: Swat. Hazara. Kashmir 610-1520 m. **D**: W Himalaya: E Afgh. - Nepal.

Potamogeton:

The species of *Potamogeton* grow submerged or with floating leaves in ± freshwater lakes, ponds, ditches or not too fast flowing streams and rivers. Some tolerate certain salt contents (*P. pectinatus, P. amblyphyllus, P. nodosus*). Suitable habitats are not many in the Karakorum, which is due to the dry climate, high relief energy, absolute altitude, and the resulting scarcity or high salinity of permanent water-bodies. Since the determination of reduced vegetative specimens is often impossible and the systematic position of several taxa is unsettled (especially of the subgenus *Coleogeton*), generally it is not possible to give any more detailed ecological data for the few records from the Karakorum.

Key to *Potamogeton*:

1. Stipular sheath adnate to the leaf forming a sheathing leaf base. Leaves linear to filiform (Subgen. *Coleogeton*) **2**
\+ Stipular sheaths free from the base. Leaves mostly broader (Subgen. *Potamogeton*) **3**
2. Leaf apex acute; stipular sheaths open, convolute. Fruitlets 3-5 mm long ..... **P. pectinatus**
\+ Leaf apex broadly rounded; leaves 0.5-1.5 mm broad; stipular sheaths tubular towards the base. Fruitlets 3-3.5 mm long ..... **P. amblyphyllus**
(Leaf apex gradually narrowed, obtuse; leaves usually less than 1 mm broad. Fruitlets 2-2.8 mm long: *P. filiformis*)
3. Leaves all alike, submerged **4**
\+ Leaves mostly dimorphic, with coriaceous floating leaves **7**
4. Leaves narrowly linear, less than 3 mm broad ..... **P. pusillus**
\+ Leaves broadly linear to ovate, more than 3 mm broad **5**
5. Leaves shortly petiolate; stipules 2.5-5 cm long ..... **P. lucens**
\+ Leaves sessile; stipules caducous, less than 2 cm long **6**
6. Leaves cordate-amplexicaul, ovate to lanceolate ..... **P. perfoliatus**
\+ Leaves not amplexicaul, oblong to broadly linear ..... **P. crispus**
7. Submerged leaves narrowly linear, with a broad band of lacunae bordering the midrib; lamina of floating leaves up to 3.5 cm long. Spikes few-flowered ..... **(P. octandrus)**
\+ Submerged leaves broader or reduced to narrowly linear, opaque phyllodes; lamina of floating leaves more than 3.5 cm long. Spikes many-flowered **8**
8. Floating leaves with a discoloured joint at the top of the petiole; submerged leaves, if present, reduced to narrowly linear, opaque phyllodes ..... **P. natans**
\+ Floating leaves without a discoloured joint at the top of the petiole; submerged leaves, if present, narrowly lanceolate to elliptic-oblong **9**
9. Submerged leaves petiolate, lanceolate or broadly lanceolate-oblong ..... **P. nodosus**
\+ Submerged leaves sessile, linear-lanceolate to elliptic **10**
10. Apices of submerged leaves obtuse, margin entire ..... **(P. alpinus)**
\+ Apices of submerged leaves acute or acuminate, margin minutely denticulate ..... **(P. gramineus)**

* **Potamogeton alpinus** BALBIS 1804 - **A**: ?Deosai: Gulteri - Sumbal in Shingo Vy. (Ann.Cat.Pak.). [?]Kashmir: Dal Lake. **D**: Eurasia, N America.

D: NE Anatolia, Caucasus - Afgh., Pakistan, C. Asia, Tibet, China. *Centr.As.*

N: Most records of *P. filiformis* from C. & S Asia probably belong here, as well as the record of "*Zostera marina*" (a strictly marine plant !) of DEASY (1901), occasionally repeated in literature. *P. amblyphyllus*, under the above concept, is very variable as regards the width of the leaves, which apparently is positively correlated with the salt content. Large beds of dead plants entirely consisting of this species appear to be a common feature of the Tibetan lakes. It ascends to 5300 m in C.Tibet (Tangula Shan, *Dickoré*).

6 Vegetation - Vegetation

Die Vegetation des Karakorum und angrenzender Gebiete ist mit außergewöhnlich scharfen Grenzen altitudinal (MEEBOLD 1909, DICKORÉ 1991) und standörtlich (STEWART 1982) stark differenziert. Trotzdem bestehen grundsätzliche Schwierigkeiten in der Beschreibung und Definition der Vegetationstypen, deren Ursachen zu einem Teil in den unterschiedlichen Sippenfassungen verschiedener Autoren liegen.

6.1 Vegetationskundliche und pflanzensoziologische Arbeiten - Works on Vegetation and Phytosociology

Vegetationskundliche Pionierarbeiten leistete im Nanga Parbat-Massiv TROLL (1939) mit einer detaillierten Vegetationskarte, die im gesamten Himalaya bis heute ihresgleichen sucht. Die Bestimmungsarbeiten waren allerdings nicht abgeschlossen und sein Belegmaterial ist im Krieg anscheinend vollständig in Berlin verbrannt. Daher ist die taxonomische Grundlage seiner Arbeit teilweise unsicher. Die Monographie von SCHICKHOFF (1993) bildet mit einer großmaßstäblichen Vegetationskarte einen Anschluß an das Kaghan Vy. der Himalaya-Südabdachung. Für den Zentral-Karakorum bietet HARTMANN (1968, subalpine Stufe) und HARTMANN (1972, alpine Stufe), eine auch taxonomisch (HARTMANN 1966, 1984) hervorragend abgesicherte Grundlage.

Gute Vegetationsbeschreibungen für Teilgebiete des Karakorum finden sich weiterhin bei PAFFEN, PILLEWITZER & SCHNEIDER (1956), WEBSTER & NASIR (1965) und LLOYD & LLOYD (1968). Die Arbeiten von AHMED & QADIR (1976) und AHMED (1976) aus der Talstufe des S & W Karakorum entbehren demgegenüber einer reproduzierbaren taxonomischen Grundlage. DURANI, SINGH & KACHROO (1975) geben eine Beschreibung der Vegetation von Ladakh, die von HARTMANN (1983, 1987) in Tabellenform belegt und übersichtlich gegliedert wird.

Die zusammenfassende Darstellung der dreidimensionalen Zonierung der Flora des Himalaya von SCHWEINFURTH (1957) ist bis heute gültige Grundlage. Die "alpine Steppe" des Tibetanischen Plateaus und des größten Teils des Karakorum bleibt jedoch ungegliedert. WISSMANN (1959, 1960-1961) gibt einen Überblick über den Zusammenhang zwischen den Schneegrenzhöhen und Vegetationsstufen. ZHANG JINGWEI & al. (1981) untersuchen die latitudinale Differenzierung der Vegetation Tibets und deren klimatische Grundlage. Die umfassendste Vegetationsmonographie aus dem zentralen Himalaya ist die Arbeit über den Langtang-Himalaya von MIEHE (1990); eine allgemeine Übersicht gibt MIEHE (1991). Für Tibet sind neben der chinesischen Monographie (ZHANG JINGWEI & al. 1988), die Arbeiten von WANG JINTING (1981, 1987, 1988) sowie MIEHE (1988) zu nennen.

Die Vegetation von Chitral behandeln in Einzelaspekten KERSTAN (1937), BEG & BAKHSH (1974) und KHAN (1978). Insbesondere die *Quercus*-Waldstufe von Swat untersuchen BEG & KHAN (1980) sowie BEG & KHAN (1984); temperierte Wälder beschreibt AHMED (1988). AITCHISON (1864) und MOHAN (1955) beschreiben die Vegetation des Punjab. Grasland- und Wiesengesellschaften des W Himalaya charakterisieren JOHNSTON & EJAZ HUSSAIN (1963), GUPTA & NANDA (1970), KAUL & SARIN (1971) und GUPTA (1974).

WALTER (1974) bietet einen Überblick über die Vegetation Zentralasiens. Die Vegetationsgliederung Afghanistans ist in zahlreichen Arbeiten untersucht worden (LINCHEVSKY & PROZOROVSKY 1949, VOLK 1954, NEUBAUER 1955, FREITAG 1971a, FREITAG 1971b, GILLI 1977, BRECKLE 1971, 1974, 1988, BRECKLE & FREY 1988), darunter am umfassendsten wohl von FREITAG (1971a). Die außerordentlich reichhaltige Flora Afghanistans erschwert die Vergleichbarkeit, da eine einheitliche floristische Grundlage fehlt. Ähnliches gilt für Tadzhikistan und den Pamir, der von zahlreichen russischen Autoren untersucht wurde. Eine Vegetationskarte findet sich im "Atlas of the Tadzhik Soviet Socialist Republic". Vegetationskarten von China präsentieren SONG YONGCHANG (1983) und HOU (1984).

6.2 Die aktuelle Vegetation des Karakorum - Actual Vegetation of the Karakorum

"I find it extremely difficult to describe in an adequate manner the extreme desolation of the most barren parts of Tibet, where no luxuriant forest or bright green herbage softens the nakedness of the mountains, but everywhere the same precipices, heaps of rocks, and barren monotonous deserts meet the eye."
(T.THOMSON 1852: 376)

Die Vegetation des CN Karakorum kann aus eigener Ansicht relativ ausführlich beschrieben werden. Für die übrigen Gebiete werden auf die existierende Literatur und die geplante Vegetationsmonographie (MIEHE in prep.) verwiesen und einige aus der vorliegenden Bearbeitung der Monocotyledoneae gewonnene Daten dargelegt.

6.2.1 Zentraler Nord-Karakorum - CN Karakorum

Die Vegetation der Gebirgswüstenregion des CN Karakorum ist sehr artenarm, gering differenziert und stark kontrahiert. Große Gebiete sind nahezu frei von höheren Pflanzen, Moosen und Flechten. Eine Waldstufe fehlt völlig; Steppen-, Polsterpflanzen- und Rasengesellschaften kommen nur lokal vor. Dennoch zeigt die Vegetation eine außerordentlich deutliche altitudinale Zonierung (DICKORÉ 1991). Die folgende Schilderung basiert im wesentlichen auf eigenen Untersuchungen in K2-North. Die Vegetation von Braldu im W, im Bereich des Shimshal P., einer wesentlichen Depression der Hauptkette, ist sicher reicher und differenzierter. Shaksgam im E ist kaum bekannt, aber jedenfalls noch ärmer als K2-North.

6.2.1.1. Subalpine Stufe - Subalpine belt

Uniforme *Krascheninnikovia ceratoides*-Wüsten beherrschen die Vegetation des CN Karakorum unterhalb 4200-4400 m Meereshöhe und sind gegen die etwas reicheren alpinen Gesellschaften scharf abgegrenzt. Auf vergleichsweise günstigen (Wasserzuschuß-) Standorten beträgt die Artenzahl höherer Pflanzen 4-5 / 100 m^2, die Vegetationsbedeckung überschreitet selten 15 % der Fläche und liegt meist unter 5 %. Moose und Flechten fehlen oft praktisch vollständig. Charakteristische Arten sind *Stipa caucasica* subsp. *glareosa*, *Tanacetum fruticulosum* und *Oxytropis microphylla*. *Ephedra intermedia* ist unterhalb 4000 m häufig und tritt oft als alleiniger Besiedler in Felsschluchten auf; *K. ceratoides* bildet "Einartgesellschaften" am Fuß der gigantischen vegetationslosen Schutthalden. *Berberis ulicina* kennzeichnet eine etwas reichere Halbwüstenvegetation auf Wasserzuschußflächen mit sehr lokalen Vorkommen von *Rhamnus prostrata*, *Ribes orientale* und *Juniperus turkestanica*.

Grund- und quellwasserabhängige Pflanzengesellschaften sind, offensichtlich aufgrund extremer Temperatur- und Wasserstandsschwankungen, aber auch katastrophaler Flutereignisse durch Gletscherseeausbrüche, auf sehr kleine Flächen beschränkt. Eine etwas größere Ausdehnung erreichen nur *Myricaria bracteata*-Auengebüsche. In geschützten Buchten der Talböden und an den wenigen Quellaustritten kommen, sehr lokal und meist scharf begrenzt, relativ artenreiche Quell- und Flachmoorrasen vor (*Carex pseudofoetida*, *Carex orbicularis*, *Carex microglochin*, *Kobresia royleana*, *Blysmus compressus*, *Puccinellia tenuiflora*, *Triglochin palustre* und *T. maritima*), sehr selten *Salix pycnostachya*. Vereinzelte Pflanzen oder kleinere Siedlungen von *Artemisia santolinifolia*, *Lonicera asperifolia*, *Crepis flexuosa*, *Corydalis adiantifolia* s.l., *Arnebia guttata*, *Rheum tibeticum*, *Elymus nutans* kennzeichnen die mobilen Geröllflächen der Flußterrassen und Gletschervorfelder. *Calamagrostis pseudophragmites* und *Leymus secalinus* bilden stellenweise wiesenähnliche Bestände auf geschützteren sandigen Standorten im Bereich verfügbaren Grundwassers.

© Biologiezentrum Linz/Austria; download unter www.biologiezentrum.at

6.2.1.2 **Alpine Stufe** - Alpine belt

Ein unterbrochener, nur an weniger steilen und nicht direkt S-exponierten Hängen gut ausgebildeter Steppengürtel mit *Festuca olgae* kennzeichnet die untere alpine Stufe (ca. 4300-4600 m). Die Artenzahl mittlerer Standorte ist, bedingt durch das Zusammentreten subalpiner und alpiner, aber auch mehrerer ± auf den übergangsbereich beschränkter Taxa (*Allium carolinianum*, *Carex alexeenkoana*, *Poa lipskyi*, *Astragalus nivalis*, *Astragalus webbianus*), in dieser Höhenstufe am größten (bis ca. 15-20 Arten /100 m^2).

Die Vegetation der mittleren alpinen Stufe mit durch *Tanacetum tibeticum* (*Ajania tibetica*) gekennzeichneten lückigen Chamaephyten- und Hemikryptophyten-Gesellschaften ist relativ artenreich, aber bereits auf schmale gletscherbegleitende Streifen beschränkt oder in inselartige Einzelbestände aufgelöst, die daher auch als extrazonale Standorte innerhalb der alpinen Wüste aufgefaßt werden können.

Tanacetum tibeticum, *Thylacosperum caespitosum*, *Rhodiola fastigiata*, *Rheum spiciforme*, *Potentilla (Dasiphora) dryadanthoides*, *Androsace flavescens*, *Elymus schrenkianus* und *Festuca tibetica* sind häufige Schuttbesiedler, die bis in die hochalpin-subnivale Stufe aufsteigen. *Oxytropis chiliophylla*, *Dracocephalum heterophyllum* und *Tanacetum pyrethroides* scheinen deutlicher auf die mittlere alpine Stufe beschränkt. Auffällig ist eine Hochstaudengesellschaft auf etwas stabilisiertem Blockschutt mit *Carex nivalis* und *Delphinium brunonianum*. Alpine Steppen und Rasen sind nur sehr kleinflächig ausgebildet und wohl durch die hohe Reliefenergie begrenzt. *Poa attenuata* und *Leontopodium nanum* sind häufig, *Poa lipskyi*, *Stipa subsessiliflora*, *St. purpurea*, *Lagotis decumbens* kommen nur in geschützten Mulden vor.

Die standörtliche Differenzierung der alpinen Vegetation ist generell gering. Die meisten Arten besiedeln je nach Meereshöhe und Exposition unterschiedliche Fels-, Schutt- oder rasenähnliche Standorte ("Relative Standortskonstanz"). Im Gegensatz zur subalpinen Stufe gibt es jedoch einige spezialisierte Chasmophyten (*Saxifraga pulvinaria*, *Eritrichium* spp., *Viola biflora*, *Dolomiaea macrocephala*). Ebenfalls überwiegend auf die N-Expositionen beschränkt sind lithophytische Flechten und felsspaltenbesiedelnde Laubmoose artenreich vertreten.

6.2.1.3 **Hochalpin / subnivale Stufe** - High alpine / subnival belt

Die "Solifuktionsakrobaten" *Saussurea gnaphalodes* und *Sibbaldia tetrandra* kennzeichnen die Frostschuttstufe (free gelifluction belt) oberhalb (4400-) 4700 m bis zur Obergrenze des Vorkommens höherer Pflanzen (ca. 5200 m; Schneegrenze ca. 5500 m). Seltener sind *Lagotis globosa*, *Silene gonosperma*, *Waldheimia tomentosa*, *Waldheimia tridactylites*. Die innerhalb gewaltiger vegetationsfreier Schutt- und Felsmassen nur noch sehr vereinzelten hochalpinen Pflanzensiedlungen können lokal auch zu geschlossenen und relativ artenreichen Rasenflecken (*Carex borii*, *Kobresia karakorumensis*, *Stipa concinna*, *Potentilla pamirica*, *Gentianella pygmaea*) zusammentreten.

6.2.2 **Zentraler Süd-Karakorum** - CS Karakorum

Die Vegetation des repräsentativen Biafo-Gebietes wurde von HARTMANN (1968, 1972) ausführlich dargestellt; WEBSTER & NASIR (1965) geben eine erste Übersicht über Saltoro. Generell ist die Vegetation stärker differenziert als auf der Nordabdachung. *Tab. 1* gibt eine Übersicht analoger Vegetationsformationen der N- und S-Abdachungen des Zentral-Karakorum. Alpine Rasengesellschaften bedecken im CS relativ große Flächen und sind floristisch wesentlich reichhaltiger als im CN Karakorum. Der westliche CS Karakorum ist Waldgrenzgebiet, in dem unter optimalen Bedingungen erste Vorposten subalpiner Gehölze (*Juniperus turkestanica*, *Betula utilis* subsp. *jacquemontii*) auftreten, ohne jedoch größere Bestände zu bilden. In östlicher Richtung ist nach dem vorliegendem floristischen Material ebenfalls eine abnehmende Differenzierung der Vegetationsbedeckung zu erwarten.

© Biologiezentrum Linz/Austria; download unter www.biologiezentrum.at

Die kollinen Wüstensteppen erreichen unterhalb 2000 (-2700) m in Baltistan noch die tiefsten Taleinschnitte des CS Karakorum (*Artemisia fragrans*). Montane *Artemisia brevifolia*-"Strauchsteppen" (*Koeleria cristata*, *Piptatherum gracile*, *Poa sterilis*) sind unterhalb von ca. 3100 m weit verbreitet, *Juniperus excelsa* kommt nur vereinzelt vor und bildet nur lokal offene Steppenwälder. Auf strikte N-Exposition beschränkt keilt die subalpine *Betula utilis* subsp. *jacquemontii*-Stufe gegen 3100-3600 m aus, ebenso *Juniperus communis* subsp. *sibirica*-Zwergstrauch-Gesellschaften. *Salix karelinii*-Gebüsche sind ebenfalls auf N-Expositionen der unteren alpinen Stufe beschränkt (3700-4000 m), alpine Steppen und Rasengesellschaften dominieren zwischen 3900 und 4300 m (-4800) (*Carex borii*, *Colpodium baltistanicum*). Die Untergrenze der subnivalen Frostschuttstufe liegt etwa zwischen 4300 und 4700 m.

6.2.3 **Nord-Karakorum** - N Karakorum

Die Kunlun-Hauptkette schirmt den größten Teil des N Karakorum gegen den Lößgürtel um das Tarim-Becken und die von NW übergreifenden höheren Niederschläge ab. Die Vegetation der zentralasiatischen Wüsten und Lößsteppen in Hochlagen der Kunlun-Nordabdachung (*Picea schrenkiana*-Wälder: Kongur) greift daher nur in stark verarmter und abgewandelter Form in den N Karakorum über.

Die alpinen Steppen des N Karakorum vermitteln zwischen denen Tibets und des Tian Shan. Besonders charakteristisch scheint eine „alpine Polstersteppe", die sich durch *Poa attenuata* und *Oxytropis densa* kennzeichnen läßt. *Oxytropis ampullata* und *O. chionobia* sind weitere polsterförmige und weißfilzige Arten von lokaler Bedeutung. Neben *Stipa purpurea* und *Stipa subsessiliflora* kommen vor allem im Nordwesten eine Reihe E Pamirischer Elemente vor (*Calamagrostis anthoxanthoides, Colpodium leucolepis, Acantholimon diapensioides*). *Festuca valesiaca* subsp. *hypsophila*-Steppenrasen vermitteln ebenfalls zu Vegetationsformen des E Pamir. In ± geschlossenen *Cyperaceae*-Rasen in der oberen alpinen Stufe dominieren meist die weitverbreiteten *Carex pseudofoetida* und *Kobresia capillifolia*.

Subalpine und montane Vegetationstypen greifen nur in den großen Durchbruchstälern (Gez, Yarkand, Karakash) geringfügig und von W nach E abnehmend in den N Karakorum über. Die subalpinen *Krascheninnikovia ceratoides*-Wüsten des N Karakorum gleichen offensichtlich weitgehend denen des CN Karakorum (s.o.). *Sympegma regelii* und *Nitraria schoberi* als Kennarten der montanen Wüsten finden ihre südliche Verbreitungsgrenze am Fuß des N Karakorum (unterhalb 3600-3800 m).

6.2.4 **West-Karakorum** - W Karakorum

Vegetation und Flora des W Karakorum weisen aufgrund der relativ günstigen und extrem vielfältigen klimatischen Bedingungen die höchste Diversität auf. Die S und W Flanken des Rakaposhi-Haramosh-Massivs (Gilgit, Hunza) werden offensichtlich noch von durch das Indus-Durchbruchstal kanalisierten Sommermonsun-Ausläufern erreicht. Die Bedingungen oberhalb der montanen Stufe sind subhumid bis humid. Die übrigen Gebiete sind als semihumid - semiarid einzustufen; nur die direkte Umgebung des stark abgeschirmten Khunjerab P. ist arid (WEIERS 1993, S. MIEHE mskr.) und der Region der zentralasiatisch-alpinen Steppen des CN und N Karakorum zuzurechnen. Im äußersten W (Ghizar, Yasin) macht sich ein gewisser Irano-Turanischer Einfluß bemerkbar (Winterregen). Die altitudinale Vegetationgliederung des W Karakorum ist vergleichsweise komplex und kann hier nur kurz umrissen werden.

6.2.4.1 **Kolline Stufe** - Colline belt

Eine durch tropisch-subtropische Elemente geprägte Halbwüsten-Vegetation (*Stipagrostis plumosa*, *Aristida adscensionis*, *A. cyanantha*, *Pennisetum orientale*, *Artemisia fragrans*, *Haplophyllum gilesii*) charakterisiert die kolline Stufe im SW Karakorum, Bewässerungs-Oasen sind scharf begrenzt. Die "Federgras-Wüstensteppe" (TROLL 1939) enthält keine *Stipa*-Arten; *Stipagrostis plumosa* ist kennzeichnend. Die Obergrenze der kollinen Stufe liegt bei etwa 2400 m (Ishkoman, Gilgit, Hunza, Skardu, Shigar). Einzelne

© Biologiezentrum Linz/Austria; download unter www.biologiezentrum.at

Vertreter der subtropisch-collinen Flora erreichen an klimatisch begünstigten Standorten noch etwa die 2700 m-Isohypse (Batura, Eingang Shimshal Vy.).

6.2.4.2 **Montane Stufe** - Montane belt

Die aride untere montane Stufe charakterisieren *Haloxylon thomsonii* und *Daphne mucronata*; vereinzelt kommen *Berberis lycium* und *Pinus gerardiana* vor. Oberhalb ca. 2700 m dominieren „Zwergstrauch-Steppen" (*Artemisia brevifolia, Koeleria cristata, Poa sterilis, Piptatherum gracile*) und auf Schatthängen relativ weit verbreitet Steppen-Wälder (*Juniperus excelsa*). *Pinus gerardiana* kommt nur sehr lokal vor (Vorposten in Hunza bei Chaprot). Subhumide Bedingungen der äußeren Ketten charakterisieren *Pinus wallichiana*-Wälder. Zwischen 3000 und 3300 m kommen auf N-Expositionen unter optimalen hygrischen Bedingungen geschlossene *Picea smithiana*-Wälder vor, *Pinus wallichiana* mit einer breiteren ökologischen Amplitude ist meistens beigemischt. Die *Picea smithiana*-Wälder enthalten eine artenreiche und eigenständige Flora mit zahlreichen temperat Eurasiatischen (*Goodyera repens*), Himalayischen (*Neottia listeroides, Polygonatum geminiflorum, Pyrola karakoramicola*) und auch einigen endemischen Arten (*Carex oligocarya, Allium gilgiticum, Poa gilgitica*). Mehr oder weniger auf die reinen *Pinus wallichiana*-Wälder und mit einem weiteren Höhenspektrum greifen z.B. *Polygonatum leptophyllum* und *Orthilia secunda* über. *Abies webbiana* findet sich nur (? noch) in Einzelexemplaren (Kar Gah, Baghrot Vy., ?Naltar Vy.). REPP (1963) gibt für das Naltar Vy. auch *Cedrus deodara* an, weder DUTHIE (1893) noch andere erwähnen die Himalaya-Zeder von dort. *Cedrus deodara* ist im Indus Vy. knapp außerhalb des Karakorum weit verbreitet (bis Chilas, Astor), ein Vorposten im floristisch reichhaltigen Naltar Vy. ist daher nicht ausgeschlossen. Ähnliches gilt für *Quercus baloot*, die in der Gor-Region (Chilas) noch ausgedehnte Bestände besitzt.

6.2.4.3 **Subalpine Stufe** - Subalpine belt

Geschlossene *Betula utilis* subsp. *jacquemontii*-Wälder mit einer Untergrenze bei ca. 3500 m charakterisieren die humide subalpine Stufe, in Lawinenbahnen reichen *Betula*-Krummholzgebüsche weit abwärts in die montane Stufe. Die feuchtesten Bereiche, Schatthänge im Rakaposhi-Massiv zwischen 3600 und 3800 m, nehmen subalpine Gebüsche aus *Rhododendron anthopogon* und *Salix* spp. ein. Im inneren subhumid-subariden Gebiet wird der montane *Juniperus excelsa* in der subalpinen Stufe durch *Juniperus turkestanica*, verbreitet zwischen (3600-) 3700-3900 (-4100) m, ersetzt. *Salix karelinii*-Gebüsche auf Schatthängen, im W (Yasin) ein breiter Zwergstrauch-Gürtel mit *Juniperus communis* subsp. *sibirica* (3200-3900 m), vermitteln zur alpinen Stufe.

6.2.4.4 **Alpine bis subnivale Stufe** - Alpine to subnival belts

Alpine Rasen sind in der alpinen Stufe des äußeren W Karakorum großflächig und artenreich entwickelt (*Kobresia nitens, Poa alpina, Carex stenocarpa, Festuca alatavica*), gegen die subariden inneren Bereiche dominieren „alpine Steppen" (*Festuca olgae, Kobresia capillifolia, K. schoenoides*). Arten wie *Carex borii, Kobresia karakorumensis, Puccinellia kashmiriana* charakterisieren die Untergrenze der alpinen Frostschuttstufe bei ca. 4000-4200 m.

6.2.5 **Süd-Karakorum** - S Karakorum

Die breite subhumide Höhenstufe des SW Karakorum keilt östlich des Deosai-Plateaus aus. Insgesamt vollzieht sich indusaufwärts von Skardu nach Leh ein starker Floren- und (physiognomisch weniger auffälliger) Vegetationswandel von warm- zu kalt-ariden Bedingungen. *Capparis spinosa* als Vertreter der subtropisch-ariden Talstufe steigt im Indus Vy. etwa bis 3200 m auf. Letzte Vorposten von *Juniperus excelsa* finden sich im Wakha-Vy. (Suru) und im heiligen Hain von Himis Shukpa (Indus Vy.). Diese „Reliktstandorte" bieten anscheinend auch besonders günstige mikroklimatische Voraussetzungen, wenn

© Biologiezentrum Linz/Austria; download unter www.biologiezentrum.at

auch die potentielle Verbreitung der *Juniperus*-Wälder eventuell etwas weiter wäre. Die montanen *Haloxylon thomsonii*-Schutthalbwüsten reichen etwa bis 3600 m aufwärts. *Artemisia brevifolia*-Strauchsteppen sind oberhalb 3600 m weit verbreitet, viele der eher subhumid verbreiteten Arten fallen jedoch aus. Die alpine und subnivale Stufe N des Indus ist relativ wenig bekannt; anscheinend finden Arten der humiden alpinen Stufe (z.B. *Carex stenocarpa*) ebenfalls ihre Verbreitungsgrenzen in der mittleren Ladakh-Kette. Die durch hohe Anteile weitverbreiteter Eurasiatischer und Holarktischer, aber auch Tibetanischer Elemente charakterisierte Vegetation von Ladakh wurde in mehreren Arbeiten ausführlich dargestellt (z.B. HARTMANN 1983, 1984, 1987, BILLIET & LÉONARD 1986), so daß hier auf nähere Ausführungen verzichtet werden kann.

6.2.6 **Ost-Karakorum** - E Karakorum

Die Vegetation des E Karakorum entspricht als derem westlichen Fortsatz im wesentlichen der W Tibets (Changtang). Ausgedehnte hochalpin-subnivale Frostschuttwüsten auf Grundmoränen und Sandern im Permafrostbereich sind außerordentlich artenarm und dünn von höheren Pflanzen besiedelt. *Carex moorcroftii*, *Carex sagaensis*, *Kobresia robusta*, *Puccinellia himalaica*, *Krascheninnikovia compacta*, *Saussurea thomsonii*, *Thylacospermum caespitosum* kennzeichnen vielleicht den nördlichen Teil (Changtang). Der zum Indus entwässernde Süd-Teil ist etwas artenreicher (z.B. *Kobresia pygmaea, Poa tibetica, Trikeraia hookeri, Saussurea glanduligera, S. thomsonii, Artemisia stracheyi, Artemisia minor*); geschlossene *Kobresia pygmaea*-Rasen, die weiter östlich zonal dominieren, kommen im östlichen Grenzgebiet des Karakorum nur sehr kleinflächig auf Grundwasser-Standorten vor.

7 **Phytogeographie und Verbreitungsmuster** - Phytogeography and distribution patterns

Pionierarbeiten zur Pflanzengeographie von W China, E Tibet und des Himalaya leistete DIELS (1913, 1942). CHATTERJEE (1939) gibt eine erste Übersicht über die endemische Flora des Indischen Subkontinents. Die Standardarbeiten von HULTÉN (1962) und MEUSEL & al. (1965-1992) vertieften auch das Verständnis der Sino-Himalayischen Diversitätszentren vieler Gruppen der Zirkumpolaren und Eurasiatischen Flora. Die Pflanzengeographie des W Himalaya wird von MEUSEL & SCHUBERT (1971) monographisch dargestellt. MEUSEL (1971, 1972) und WENDELBO (1971) untersuchen die Beziehungen zwischen den semiariden Mediterranen und Irano-Turanischen Florengebieten und dem Himalaya / Hochasien. ZHENG DU (1983) präsentiert eine chorologische Analyse der Flora von Tibet. MIEHE (1990) und SCHICKHOFF (1993) diskutieren phytogeographische Charakteristika des C. und W Himalaya.

Der Karakorum trennt als eine der mächtigsten Gebirgsbarrieren Asiens die fundamental unterschiedlichen Zentralasiatischen, Irano-Turanischen und Sino-Himalayischen Klima- und Vegetationsregionen. Exakte Grenzziehungen sind im Karakorum durch eine artenarme, vertikal und horizontal jedoch stark differenzierte Flora erschwert. Die Chorologie der Karakorum-Flora muß daher mindestens auf den drei Ebenen der (1.) Phytogeographischen Regionen, (2.) Geobotanischen Elemente und (3.) Regionalen Verbreitungsmuster untersucht werden. Da sowohl über die Hierarchie der phytogeographischen Gliederung Asiens als auch über die Benennung und Abgrenzung der phytogeographischen Regionen beträchtliche Differenzen bestehen, sind die folgenden Umschreibungen als informelle, an den Verhältnissen des Übergangs- und Grenzgebiets Karakorum orientierte Übersicht gedacht. Komplexere Definitionssysteme können in diesem Rahmen nicht diskutiert werden. Ähnliches gilt für die Einordnung einzelner Sippen, die zudem stark von der taxonomischen Abgrenzung abhängt. CLAYTON & COPE (1980) bieten ein System für die altweltlichen *Gramineae*.

© Biologiezentrum Linz/Austria; download unter www.biologiezentrum.at

7.1 **Phytogeographische Regionen** - Phytogeographical regions

7.1.1 **Zentralasiatische Region** - Central Asiatic region

Die Zentralasiatische Region wurde von GRUBOV (1963) scharf abgegrenzt. Sie umfaßt drei unterschiedliche Teilgebiete. Holzige Vertreter der *Chenopodiaceae* und *Zygophyllaceae*, die für die Tieflands- und Gebirgs-Strauchsteppen und Wüsten der Dzungarischen und der Kashgaro-Mongolischen Subregionen charakteristisch sind, fehlen fast völlig in der Hochgebirgsvegetation der Tibetanischen Subregion.

7.1.1.1 **Dzungarische Subregion** - Dzungarian subregion

Flora und Vegetation der Dzungarischen Subregion vermitteln zu den Wüsten Mittelasiens, zum Winterregengebiet der Irano-Turanischen Region und zum Euro-Sibirischen Waldgebiet in den Gebirgen. Charakteristisch für die Höhenstufen ist eine starke Durchmischung von alpinen und Steppenelementen (WALTER 1975). Einige Dzungarische Elemente erreichen im S noch die kashgarische Pforte (*Krascheninnikovia ewersmanniana*) und die Nordabachungen des Alai und westlichsten Kunlun Shan (King Ata Tagh, Kongur Shan). *Picea schrenkiana*-Wälder, die sich lokal als isolierte Vorposten auf der Kongur-Nordseite zwischen (2100) 2700-3000 (3400) m finden (SKRINE 1925), enthalten im Unterwuchs kennzeichnende Arten wie *Carex alaica, Carex turkestanica* und *Elymus tschimganicus*.

7.1.1.2 **Kashgaro-Mongolische Subregion** - Kashgaro-Mongolian subregion

Die Kashgarische Flora ist im wesentlichen ein artenarmer, weit nach Westen vorgeschobener Teil der Mongolischen Wüstenflora. Kashgaro-Mongolische Elemente dominieren rings um das Tarim-Becken bis in mittlere Meereshöhen (ca. < 3000 m, vgl. GRUBOV 1963, DICKORÉ 1991) der Kunlun-Nordabdachung. Im Karakorum sind sie deutlicher nur im Bereich der größeren Durchbruchs-Täler nach N repräsentiert (Taxkorgan, Yarkand, Karakash). Typische und häufige montane Elemente sind *Nitraria schoberi*, *Sympegma regelii* und *Peganum harmala* (auch mediterran-vorderasiatisch); seltener ist *Cynomorium mongolicum*, ein Parasit auf *Nitraria*. Ausgedehnte Steinwüsten (Gobis) am Gebirgsrand sind durch microphylle Sträucher wie *Haloxylon ammodendron*, *Calligonum* spp., *Zygophyllum* spp. und *Ephedra przewalskianum* charakterisiert. Therophyten fehlen, mit Ausnahme einiger ± sukkulenter Sommerannueller (*Zygophyllum lehmannianum*, *Halogeton glomeratus*, *Salsola* spp., *Atriplex sibirica*, *Bassia dasyphylla*) Die Endemiten *Poacynum hendersonii* und *Myricaria pulcherrima* sind an Oasen und sandige Grundwasserstandorte der Tieflandswüsten gebunden. Auf subhumide höhere Lagen beschränkt sind *Caragana polourensis*, *Reaumuria soongorica* und die Gräser *Stephanachne pappophorea* und *Stipa breviflora*. Die alpine Flora der Kunlun-Nordabdachung ist sehr unvollkommen bekannt und offensichtlich artenarm. Sie enthält jedoch einige in den Hochgebirgen um das Tarim-Becken ± endemische Sippen (*Braya pamirica, Calamagrostis tianschanica, Carex tangulashanensis, Kobresia kashgarica*).

E Pamir und der größte Teil der Karakorum-Nordabdachung, die (in Abhängigkeit von der floristischen Ausstattung und der Meereshöhe) der Kashgaro-Mongolischen oder der Tibetanischen Subregion zugerechnet werden können, besitzen eine außerordentlich arme Flora, in der charakteristische Elemente beider Subregionen kaum vertreten sind. Häufige subalpine Arten wie *Krascheninnikovia ceratoides*, *Stipa splendens* und ein Teil der alpinen Flora bilden eine gewisse Rechtfertigung für den Einschluß der Karakorum-Nordabdachung in die Kashgaro-Mongolische Subregion. Exklaven Kashgaro-Mongolischer Elemente finden sich in gewissem Umfang in den Trockentälern des S Karakorum, von Ladakh und S Tibet (*Ephedra przewalskianum, Carex alexeenkoana, Stipa breviflora, Allium oreoprasum, Iris oxypetala*). Die Areale einiger Hochgebirgssippen erstrecken sich entlang des NW Hindukush bis etwa zum Salang P., der kontinentalste Teil des Zentralen Hindukush (Koh-i-Baba, Bamian Prov.) kann ebenfalls als Zentralasiatische Exklave aufgefaßt werden (vgl. Verbreitung von *Stipa splendens*: FREITAG 1985). Der generelle Vegetationscharakter erlaubt eventuell auch den von verschiedenen Autoren vorgenommenen Einschluß des größten Teils der Karakorum-Südabdachung in die Zentralasiatische Florenregion

© Biologiezentrum Linz/Austria; download unter www.biologiezentrum.at

(GRUBOV 1963 [Tibetanische Subregion], HARTMANN 1966, MEUSEL & SCHUBERT 1971), die Durchmischung mit Himalayischen und anderen humid-temperaten Elementen ist hier jedoch wesentlich stärker. *Nitraria schoberi* ist im S Karakorum eventuell nur eingeschleppt (HARTMANN 1966); *Sympegma regelii* ist durch den habituell und ökologisch ähnlichen, endemischen *Haloxylon thomsonii* ersetzt.

7.1.1.3 Tibetanische Subregion - Tibetan subregion

Die Hochgebirgsflora des Tibetanischen Plateaus ist sehr charakteristisch und vergleichsweise gut abgrenzbar. Problematisch sind jedoch die engen genetischen Beziehungen zur Sino-Himalayischen Flora und eine drastische Verarmung der Flora von SE nach NW. Gattungen wie *Kobresia* und *Saussurea*, aber auch zahlreiche Arten von *Primula, Androsace, Gentiana, Gentianella* (§ *Comastoma*), *Corydalis*, sind bezeichnend, besitzen aber grundsätzlich Sino-Himalayische Diversitätszentren (E Himalaya, SE Tibet, W China). Im E Karakorum ist die artenarme Frostschutt-Flora W Tibets gut repräsentiert.

Die Tibetanische Subregion kann in eine reichere S Tibetanische Domäne der oberen Indus- , Sutlej- und Tsangpo-Einzugsgebiete sowie benachbarter interner Entwässerungssysteme und eine artenarme Changtang-Domäne der abflußlosen Becken NW Tibets unterteilt werden. Die S Tibetanische Domäne erstreckt sich zwischen Gandise / Nyainqentanglha Shan und Himalaya etwa von der Umgebung von Lhasa westwärts bis Rupshu, Pangong und Changchenmo. Typische Arten hochalpiner Rasen sind *Kobresia pygmaea*, generell eine der charakteristischsten Arten des Tibetanischen Plateaus, *Carex montis-everestii* und andere. Gräser wie *Poa tibetica*, *Trikeraia hookeri, Orinus thoroldii* und *Calamagrostis holciformis* kennzeichnen die ausgedehnten Sander ehemaliger Gletscher und Frostschutt-Habitate. Die Changtang-Domäne umfaßt die Hochgebirgswüstenregion etwa vom Nam Co und W Tangula Shan bis Aksai Chin und Upper Karakash, wahrscheinlich auch Upper Yarkand. Aufgrund der extremen Meereshöhe (überwiegend > 5000 m), Trockenheit und wahrscheinlich totaler letzt-eiszeitlicher Vergletscherung, ist die Vegetation außerordentlich spärlich und artenarm. *Krascheninnikovia compacta, Saussurea thomsonii, Soroseris glomerata, Kobresia robusta, Puccinellia himalaica,* sind charakteristische Arten; andere wie *Myricaria prostrata, Hippophae thibetana, Carex moorcroftii* und *Festuca tibetica* kommen in S Tibet ebenfalls vor.

7.1.2 Sino-Himalayische Region - Sino-Himalayan region

Die Sino-Himalayische Region, in weiterem Sinne auch als "Sino-Japonische Region" bezeichnet, erstreckt sich in der hier verwendeten Abgrenzung (vgl. WARD 1927, FRASER-JENKINS 1984) von Sichuan, Yunnan, E Tibet über SE Tibet und entlang der Himalaya-Südabdachung bis an die SE-Seite des Hindukush (NE Afghanistan, Nuristan). Exklaven finden sich im äußersten W im Safed Koh / Kurram Vy., südwestwärts haben auch die Gebirge Baluchistans (Takht-i-Sulaiman, Umgebung von Quetta) Himalayischen Charakter, wenn auch stark mit Irano-Turanischen Elementen durchmischt (STEWART 1982).

Die außerordentlich reiche Sino-Himalayische Flora besitzt starke Beziehungen zu den ostasiatischen Entfaltungszentren der extratropischen (Laubwald-) Flora, aber auch zu den disjunkten Hyrkanischen und E Mediterranen Floren, und wird daher als Relikt eines im mittleren Tertiär geschlossenen subtropisch-meridional humiden Vegetationsgürtels aufgefaßt (MEUSEL & SCHUBERT 1971). Expositionsabhängig parallel verlaufen über den Himalaya Migrationswege sowohl E Asiatischer, monsun- (sommerregen-) angepaßter Sippen nach W, als auch winterregen- / sommertrockenheits-adaptierter Irano-Turanischer Elemente in umgekehrter Richtung (TABATA 1988). Das Florengefälle in E-W Richtung ist teilweise diskontinuierlich und differenziert eine West-Himalayische und Ost-Himalayische Subregion. Im Bereich des "East Nepal - Sikkim Gap" (STAINTON 1972) ist die Humidität der Himalaya-Südabdachung so hoch, daß an semiarid bis subhumide Bedingungen angepaßte Arten des offenen Geländes ausfallen, soweit sie nicht auf den hochgelegenen Tibetischen Himalaya ausweichen können. Ein Teil dieser Sippen erscheint disjunkt in den Trockentälern Bhutans wieder, oder wird dort oder im Tsangpo Vy. durch vikariierende Arten vertreten. In umgekehrter Richtung scheint die abnehmende Humidität von E nach W und die starke

© Biologiezentrum Linz/Austria; download unter www.biologiezentrum.at

Kontraktion der humiden Zone der Himalaya-Südabdachung zwischen W Nepal und Himachal Pradesh eine gewisse Differenzierung und Auslese für feuchtigkeitsangepaßte Taxa zu bedeuten.

An den Karakorum angrenzend, ist die W Himalayische Subregion im Bereich vom Indus-Durchbruchtal bis Kashmir als breiter und stark differenzierter Gürtel ausgebildet. Während die im weiteren Sinne Sino-Himalayischen Sippen des zumindest warm-semiariden Gürtels zu einem Großteil auf die Himalaya-Südabdachung beschränkt sind (*Pinus roxburghii*, *Parrotiopsis jacquemontiana*, *Quercus* spp.), erreichen zahlreiche W Himalayische Elemente den SW-Karakorum. Diese umfassen sowohl Arten der warm-ariden Talstufe (*Olea cuspidata*, *Daphne mucronata*, *Berberis lycium*, *Aristida cyanantha*), als auch der gemäßigt- bis kalt-subhumiden Höhenstufen mit Nadelwäldern (*Pinus wallichiana*, *Picea smithiana* [Verbreitungskarte: MIEHE 1990], selten *Abies webbiana*) und subalpin-alpinen Gebüschen und Rasengesellschaften (*Rhododendron anthopogon*, *Betula utilis* subsp. *jacquemontii*, *Kobresia nitens*).

7.1.3 Irano-Turanische Region - Irano-Turanian region

Das Irano-Turanische Winterregengebiet erstreckt sich von Anatolien durch SW Asien bis Tian Shan, SW Pamir, Afghanistan und dem westlichsten Pakistan. Exklaven Irano-Turanischer Steppen-Elemente finden sich auf mittleren Meereshöhen in den Trockentälern des W Himalaya (s.o.). Die Definition der Ostgrenze der Irano-Turanischen Region ist ebenso schwierig wie an ihrer Westgrenze (DAVIS 1965), da die Verteilung einzelner Sippen oft disjunkt und expositionsabhängig inselhaft ist, läßt sich aber etwa vom NW Tian Shan, W Pamir, den unteren Wakhan entlang des Hindukush-Hauptkamms relativ klar fassen. Bedeutende Einflüsse der sehr artenreichen Irano-Turanischen Flora machen sich auch im mittleren Chitral und schwächer im angrenzenden westlichsten Karakorum (Yasin) bemerkbar. Mehr oder weniger isolierte Vorposten Irano-Turanischer Sippen finden sich auch in den Tälern des SW Karakorum (*Stipa arabica*, *Carex diluta*, *Enneapogon persicus*), Kashmir und dem angrenzenden Himalayisch-Zentralasiatischem Übergangsgebiet (Astor, Dras: *Carex songorica*). Artenreiche Gattungen mit Irano-Turanischen Diversitätszentren wie *Cousinia*, *Eremostachys*, *Acantholimon*, *Tulipa*, *Eremurus* sind in der Flora des Karakorum nur mit einzelnen Vertretern, andere wie *Astragalus* und *Nepeta* ebenfalls mit vergleichsweise wenigen Arten vertreten.

7.2 Phytogeographische Elemente der Monocotyledoneae des Karakorum - Phytogeographical elements of Karakorum-Monocotyledoneae

Eine vereinfachte Aufschlüsselung der unter 5.5 bezeichneten phytogeographischen Elemente der Monocotyledoneae des Karakorum (282 Arten) ergibt für das Gesamtgebiet eine ausgewogene Verteilung (*Tab.2*). Diese unterstreicht die zentralkontinentale Position und den Grenzcharakter des Karakorum. Fig. 9 gibt die Artenzahlen und Anteile chorologischer Elemente für die Teilgebiete des Karakorum an.

Geobotanische Elemente	n = 282	%
Kosmopoliten	15	5.3
Tropisch-Subtropisch	28	9.9
Holarktisch	33	11.7
Eurasiatisch	40	14.2
Zentralasiatisch	40	14.2
Ost-Pamirisch	11	3.9
Tibetanisch	19	6.7
Himalayisch	45	16.0
Irano-Turanisch	32	11.3
Endemiten	19	6.7

7.2.1 **Kosmopoliten** - Cosmopolites

Kosmopoliten (*Cosmop.*, 5,3 %) umfassen weltweit verbreitete Wasserpflanzen und Unkräuter (z.B. *Alisma plantago-aquatica, Echinochloa crus-galli*). Sie sind vorwiegend in der collinen und montanen Stufe des S Karakorum (Indus Vy.) vertreten. Ihr weitgehendes Fehlen im N Karakorum (außer *Phragmites australis*) entspricht der größeren Meereshöhe der intramontanen Talböden im Norden (Yarkand, Karakash); die meisten Arten kommen in Kashgaria vor.

7.2.2 **Tropische und subtropisch-meridionale Elemente** - Tropical and subtropical meridionale elements

Tropisch-subtropische und meridionale Elemente (*Trop.-merid.*) sind mit 9,9 % der Gesamtartenzahl gut vertreten (z.B. *Cyperus rotundus, Chrysopogon gryllus*), jedoch nahezu ausschließlich auf die subtropisch-colline Stufe des SW Karakorum (Ghizar, Ishkoman, Gilgit, Hunza, Shigar, Skardu) beschränkt und auch dort meist selten. Sie fehlen weit überwiegend in der collinen Stufe Zentralasiens (Kashgaria). Zusammengefaßt werden in dieser Gruppe Mediterrane Elemente (*Medit.*) sowie Pantropische (*Pantrop.*), Paläotropische (*Palaeotrop.*) und Sudano-Sindische (*Sud.-Sind.*) Elemente. Innerhalb der Gruppe dominieren die Paläotropischen Elemente; Indo-Malesische Elemente fehlen vollständig.

7.2.3 **Holarktische Elemente** - Holarctic elements

Weitverbreitete Arten der gemäßigten bis arktischen Zonen der Nordhalbkugel, Holarktische und Eurasiatische Elemente, bilden zusammen einen wesentlichen Bestandteil der Flora des Karakorum, unterschieden sich jedoch in ihrer lokalen Verteilung. Holarktische Elemente (*Holarct.*, 11,7 %, z.B. *Carex atrofusca, Festuca rubra, Lloydia serotina*) mit häufig disjunkten, in Zentralasien jedoch ± kontinuierlichen "arktisch-alpinen" Arealen (Nordhalbkugel und teilweise im südlichen Südamerika) sind im Karakorum gleichmäßig, vorwiegend montan - subnival verbreitet.

7.2.4 **Eurasiatische Elemente** - Eurasiatic elements

Die Eurasiatischen Elemente (*Euras.*, 14,2 %) umfassen einen ebenfalls beträchtlichen Teil der Flora des Karakorum, konzentrieren sich aber in der (potentiellen) Fichtenwaldstufe der montanen Stufe des SW Karakorum. Die zentralasiatischen Teilareale sind häufig sehr disjunkt und eventuell als Relikte einer (interglazialen) weiteren Verbreitung der Laub- und Fichtenwälder aufzufassen. Südlich der kontinuierlichen Areale im Altai finden sich Exklaven eurasiatischer Arten auf der Nordseiten des Tian Shan und Seravshan sowie eine kleinere und artenärmere im Alai und auf der Kongur - King Ata Tagh-Nordseite (*Picea schrenkiana*-Wälder). Die Vorkommen im SW Karakorum stehen im Zusammenhang mit der bedeutenden, bis nach E Afghanistan und W Nepal ausstrahlenden Exklave von Kashmir (*Picea smithiana*-Wälder). Auch die Himalayischen Teilareale der Eurasiatischen Arten sind meist diskontinuierlich (W Himalaya - SE Tibet). Eurasiatische Elemente ohne deutlichen Schwerpunkt (*Poa nemoralis, Coeloglossum viride*) dominieren über westliche, Euro-Sibirische (*Euro-Sib.*: *Stipa pennata, Epipactis helleborine*), diese über östliche, Ost-Asiatische Elemente (*E Asiat.*: *Carex karoi, Helictotrichon hookeri, Epipactis gigantea, Spiranthes sinensis*).

7.2.5 **Zentralasiatische Elemente** - Central Asiatic elements

Zentralasiatische Elemente (*Centr.As.*, 14,2 %) und die hier aufgrund unterschiedlicher regionaler Verbreitungstendenzen gesondert aufgeführten Ost-Pamirischen und Tibetanischen Elemente dominieren insgesamt sowohl über Himalayische als auch über Irano-Turanische Elemente. Der trotz der insgesamt artenarmen zentralasiatischen Flora hohe Anteil in fast allen Teilgebieten rechtfertigt den Einschluß des gesamten Karakorum, mit Ausnahme des extremen SW (Gilgit) in die zentralasiatische Florenregion. Die Abgrenzung und Definition der zentralasiatischen Elemente ist allerdings durch ungenügende

© Biologiezentrum Linz/Austria; download unter www.biologiezentrum.at

Sippenabgrenzungen und große, in den Höhenstufen der Gebirge oft disjunkte Areale schwierig. Im systematischen Teil (5.5) wurde versucht, zwischen West-Zentralasiatischen Elementen (*W Centr.As.*, *Carex nivalis*, *Carex stenocarpa*), deren Verbreitung sich vorwiegend auf den West-Teil Hochasiens konzentriert (Tian Shan, Pamir Alai, Karakorum, Innerer W Himalaya), und den weiter verbreiteten (Kaukasus, Ural, Altai bis Tibet) eigentlichen Zentralasiatischen Elementen (*Centr.As.*, *Carex orbicularis*, *Kobresia schoenoides*, *Stipa splendens*) zu unterscheiden. Da die Gesamtverbreitung jedoch häufig unsicher bleibt und sich in der regionalen Verbreitung im Karakorum keine wesentlichen Unterschiede ergeben, werden sie hier zusammengefaßt.

7.2.6 **Ost-Pamirische Elemente** - E Pamirean elements

Ost-Pamirische Elemente (*E Pamir.*, 3,9 %) bilden einen von den Zentralasiatischen Elementen undeutlich abgegrenzten endemischen Bestandteil der Hochgebirgsflora am W Rand des Tarim-Beckens, deren Verbreitung etwa vom W Tian Shan über E Pamir bis zum NW Karakorum und W Kunlun reicht (*Puccinellia hackeliana*, *Calamagrostis anthoxanthoides*). Einige hier eingeordnete Sippen zeigen eine charakteristisch disjunkte Verbreitung bis auf die Karakorum S-Abdachung und zum W Rand Tibets (*Carex alexeenkoana*, *Stipa subsessiliflora*).

7.2.7 **Tibetanische Elemente** - Tibetan elements

Die Gruppe der Tibetanischen Elemente (*Tibet.*, 6,7 %) ist relativ gut abgrenzbar, aber heterogen. Hochasiatische, im weiteren Sinne Tibetanische Elemente (*Tibet.*) sind über große Teile des Tibetanischen Plateaus, durch den C. und N Karakorum, E Pamir bis zum C. Tian Shan verbreitet (*Stipa purpurea*, *Allium przewalskianum*). Auf das Tibetanische Plateau beschränkte Arten (*Carex moorcroftii*, *C. sagaensis*) der alpin-subnivalen Höhenstufen finden ihre Verbreitungsgrenzen im NE Karakorum. Wenige Arten charakterisieren das extrem kalt-aride Changtang-Plateau NW Tibets (*Kobresia robusta*, *Puccinellia himalaica*). S Tibetische Elemente (*S Tibet.*, *Kobresia pygmaea*, *Orinus thoroldii* sind dagegen im Gebiet ± auf das obere Indus-Einzugsgebiet beschränkte subalpin-alpine Arten, deren Verbreitungs- und vermutetes glaziales Rückzugsgebiet die Indus - Tsangpo-Depression S Tibets umfaßt.

7.2.8 **Himalayische Elemente** - Himalayan elements

Die Gruppe der Himalayischen Elemente (*Himal.*, 16,0 %) ist im Karakorum fast ausschließlich auf die Südseite beschränkt und besitzt im SW Karakorum einen ähnlichen Verbreitungsschwerpunkt wie die Eurasiatischen Elemente. Ein geringfügiges Übergreifen Himalayischer Elemente auf die Karakorum-Nordabdachung ist für die direkte Umgebung des Khunjerab P. und Shimshal P. belegt; umgekehrt ist das Übergreifen Zentralasiatischer Arten über diese einzige bedeutende Depression der Gebirgsketten zwischen Pamir und Tibet weit stärker ausgeprägt. Aufgrund der geringen Artenzahlen sind die Vorkommen Himalayischer Elemente im NE Karakorum nicht signifikant. W Himalayische Elemente (*W.Himal.*, *Kobresia nitens*, *Festuca kashmiriana*) sind mehr oder weniger trockenheitsangepaßte Arten, die kontinuierlich etwa von E Afghanistan (Nuristan) bis W Nepal verbreitet sind (vgl. *Picea smithiana*, MIEHE 1990). W Himalayische Elemente besiedeln im SW Karakorum ein weites Spektrum verschiedener Wald- (*Pinus wallichiana*, *Picea smithiana*, *Betula jacquemontii*), Gebüsch- (*Rhododendron anthopogon*, *Salix* spp.), Rasen- und Steppen-Gesellschaften sowie azonale Feuchtstandorte und strahlen gegen die Karakorum-Hauptkette aus. Monsunangepaßte Sino-Himalayische (*Sino-Himal.*, *Stipa brandisii*, *Neottia listeroides*), von SW China durch den gesamten Himalaya verbreitete Sippen, sind im Karakorum wesentlich seltener und deutlicher in der montanen *Picea schrenkiana*-Waldstufe in N-Exposition in unmittelbarer Nachbarschaft des Indus-Durchbruchs konzentriert. Das Verhältnis W Himalayischer zu Sino-Himalayischen Elementen kehrt sich auf der S-Seite des W Himalaya (Swat, Hazara, Kashmir), bei einer weit stärkeren Repräsentanz der gesamten Gruppe, offenbar um. Die direkte Umgebung des Indus-Durchbruchs (Gilgit: Kohistan-Kette, Haramosh, Rakaposhi S; Hunza: Rakaposhi N) kann insgesamt noch als Teil der Sino-Himalayischen Florenregion angesehen werden.

© Biologiezentrum Linz/Austria; download unter www.biologiezentrum.at

7.2.9 Irano-Turanische Elemente - Irano-Turanian elements

Irano-Turanische Elemente (*Ir.-Tur.*, 11,3 %, *Bromus stenostachyus, Festuca karatavica, Stipa arabica, Colchicum luteum*) sind im W und S Karakorum mit relativ vielen Arten vertreten. Sie konzentrieren sich auf offene Trockenstandorten der montanen Stufe im äußersten W (Yasin) und SW (Gilgit, Hunza), sind jedoch nirgends, außer in direkter Nachbarschaft der westlichsten Pässe, vegetationsbestimmend und fehlen auf der inneren Karakorum-Nordseite völlig. W Pamirische Endemiten (*W Pamir.*), die mit Vorposten den SW Karakorum erreichen (*Carex decaulescens, Piptatherum vicarium*) wurden in die Berechnung des Anteils Irano-Turanischer Elemente mit einbezogen.

7.2.10 Endemiten - Endemics

Der Anteil endemischer Arten (*Endem.*, 6,7 %) ist angesichts der Größe und geoökologischen Diversität des Karakorum gering und aufgrund taxonomischer Probleme eventuell noch zu hoch angesetzt. Die berücksichtigten Arten strahlen zudem häufig ± in benachbarte Gebirgssysteme aus. Das Areal der in der hochalpinen Stufe des W Karakorum verbreiteten *Carex borii*, einem der wenigen morphologisch gut charakterisierten Endemiten, strahlt zum Pamir und lückenhaft durch Ladakh bis an die Grenze von Zanskar - Himachal Pradesh aus. Ein vergleichbares, aber größeres Areal besitzt auch die ökologisch ähnliche *Kobresia karakorumensis*. Die größte Zahl endemischer Arten ist auf den S Karakorum beschränkt, die relativen Anteile sind aber auch in den artenarmen Teilgebieten vergleichbar hoch. Die isolierte *Picea smithiana*-Waldstufe in Gilgit enthält eine auffallende Konzentration von Endemiten (*Allium gilgiticum, Poa gilgitica, Carex oligocarya*; mit zunehmender Arealgröße). *Poa suruana* und *Digitaria stewartiana* kommen im mittleren Indus Vy. (Skardu, Suru) vor. Eine etwas weitere Verbreitung im inneren NW Himalaya, vorwiegend im SW Karakorum und ± zentriert um den Indus-Durchbruch, besitzen *Calamagrostis stoliczkae* und *Elymus stewartii, Elymus russellii* (montan-subalpin), *Puccinellia minuta* und *Gagea gracillima* (alpin). *Puccinellia ladakhensis* und *Puccinellia thomsonii* sind im Tibetanischen Grenzbereich zentrierte Endemiten (Oberer Indus, Rupshu) von unsicherem taxonomischen Status.

7.3 Regionale Verbreitungsmuster - Regional distribution patterns

Die Verbreitungskarten im Anhang bieten Bespiele regionaler Verbreitungsmuster, die insgesamt eine klare Klassifikation erlauben. Da diese mit der Abgrenzung der Florenregionen (7.1) und Definition der Phytogeographischen Elemente (7.2) verknüpft ist, kann die Zuordnung zu regionalen Arealtypen hier nur exemplarisch und vorbehaltlich unterschiedlicher Gesamttendenzen erfolgen.

1. Hochasiatisch alpin, *Poa attenuata*-Typ - Eine kleine, aber oft vegetationsbestimmende Artengruppe ist ± kontinuierlich und mit weiten subalp. - subniv. Amplituden über das gesamte innere Hochgebirgssystem vom E Pamir über den Karakorum bis W Tibet verbreitet, ebenso im Kunlun Shan und im Inneren Himalaya: *Carex microglochin, Kobresia royleana, Kobresia schoenoides, Elymus jacquemontii, E. schrenkianus, Poa attenuata, Potamogeton amblyphyllus.*

2. C. Karakorum, *Festuca olgae*-Typ - Die größte und für die Flora des Karakorum bezeichnendste Gruppe ist wie 1. verbreitet, mit dem Unterschied, daß die eher montan-subalpin verbreiteten oder alp.-subniv., aber auf etwas humidere Bedingungen angewiesenen Taxa gegen das Tibetanische Plateau / Changtang (bis auf die Täler S Tibets) zurücktreten: *Allium carolinianum, Blysmus compressus, Carex atrofusca, C. orbicularis, C. pseudofoetida, C. stenocarpa, C. stenophylla, Eleocharis quinqueflora, Kobresia capillifolia, K. karakorumensis, Trichophorum pumilum, Calamagrostis pseudophragmites, Elymus nutans, Eremopoa altaica, Festuca olgae, Hordeum brevisubulatum, Leymus secalinus, Stipa caucasica, St. orientalis, St. splendens, Tristeum spicatum* subsp. *himalaicum, Lloydia serotina.*

3. Tibetanisch - Die kleine, heterogene Gruppe umfaßt recht unterschiedliche Areale: N Karakorum, *Stipa purpurea*-Typ: Einige Arten sind ± kontinuierlich von W Tibet / Rupshu, Ladakh über die Karakorum-Nordabdachung bis E Pamir (Tian Shan) verbreitet: *Poa calliopsis, Stipa purpurea, Stipa subsessiliflora, Allium przewalskianum. Stipa concinna* besitzt außerdem Vorkommen im inneren Himalaya. „Karakorum-Gap", *Poa tibetica*-Typ: Diese Arten zeigen zwischen E Pamir / Kunlun Shan und Ladakh / SW Tibet eine Verbreitungslücke, die ± das gesamte Karakorum-System umfaßt: *Blysmus rufus,*

© Biologiezentrum Linz/Austria; download unter www.biologiezentrum.at

Elymus thomsonii, *Poa tibetica*, *Stipa breviflora*, *St. mongholica*. Tibetanisch, *Kobresia pygmaea*-Typ: Hochalpine Arten, die ± auf das Tibetanische Plateau beschränkt sind: *Carex moorcroftii*, *Carex sagaensis* (vikariierend zu *Carex melanantha* bzw. *C. pseudofoetida* unter 2.), *Kobresia pygmaea* und einige weitere. Die westliche Verbreitungsgrenze zeigt charakteristischerweise Vorstöße nach Rupshu und zum Karakash / Yarkand oder CN Karakorum. *Puccinellia himalaica* und *Festuca tibetica* sind noch weiter nordwestwärts verbreitet. Mehrere Arten sind auf das obere Indusgebiet / SW Tibet beschränkt: *Calamagrostis holciformis* (vikariierend zu *C. tianschanica* unter 6), *Festuca nitidula*, *Orinus thoroldii*; nur *Kobresia robusta* charakterisiert im Gebiet das Changtang Plateau / NW Tibet.

6. E Pamirisch, *Calamagrostis anthoxanthoides*-Typ - Diese charakteristische und relativ homogene Gruppe umfaßt vorwiegend alpine Taxa, die im E Pamir, NW Karakorum und W Kunlun Shan verbreitet sind und gegen die kontinentale Wasserscheide (Khunjerab, Shimshal) ihre Verbreitungsgrenze finden oder mit Vorposten auf Wakhan, NE Hindukush (Tirich Mir) und Hunza übergreifen: *Carex curaica*, *Calamagrostis anthoxanthoides*, *C. tianschanica*, *Colpodium leucolepis*, *Festuca valesiaca* subsp. *hypsophila*, *Poa lipskyi*, *Puccinellia hackeliana*, *Allium filifolium*. Einige Arten greifen stärker auf den S Karakorum oder Ladakh über: *Allium oreoprasum*, *Carex alexeenkoana*, *Elymus dentatus*.

7. S Karakorum / Ladakh, *Pennisetum flaccidum*-Typ - Die Arten dieser Gruppe besiedeln die inneren Trockentäler (mont.-subalp.) des S Karakorum. Einige Arten: *Bothriochloa ischaemum*, *Bromus pectinatus*, *Pennisetum flaccidum* zeigen neben der charakteristischen Häufung im Gilgit-Indus-Ladakh-Becken einen weiteren Schwerpunkt in den Trockentälern des äußeren Himalaya; *Pennisetum flaccidum* und *Iris oxypetala* kommen außerdem in den Kashgarischen Randgebirgen vor. Weitere Beispiele dieses Verbreitungstyps sind: *Elymus canaliculatus*, *Festuca alaica*, *Melica persica*, *Piptatherum gracile*, *Stipa himalaica* und Kulturfolger wie *Bromus tectorum* und *Vulpia myuros*. Zahlreiche weitere Arten besitzen Vorposten oder Teilareale im Indus Vy., wobei z.B. von *Bromus gracillimus*, *Koeleria argentea* das relativ humide Gilgit-Becken ausgespart wird.

8. SW Karakorum, *Poa alpina*-Typ - Eine mont.- alp. Gruppe mit mehreren gemäßigt-eurasiatischen Arten besiedelt eine breite Zone im inneren W Himalaya und W Karakorum bis etwa zum Khunjerab P., mit ± ausgeprägter Häufung auf der zentralen Karakorum S Abdachung. Die (Teil-) Areale umfassen außerdem meist W Pamir-Alai und Kongur und keilen nach SE in einen schmalen Inner-Himalayischen Streifen aus, E Pamir sowie das Ladakh-Becken werden weitgehend ausgespart: *Alopecurus arundinaceus*, *Koeleria cristata*, *Poa alpina*, *P. pratensis* subsp. *pratensis*, *P. sterilis*, *Carex melanantha*, *Carex nivalis*. *Festuca alatavica* und *F. coelestis* besitzen isolierte Teilareale im SW Karakorum.

9. SW Karakorum, Endemisch, *Carex oligocarya*-Typ - Die endemischen Areale sind unter 7.2.10 aufgeführt: *Allium gilgiticum*, *Poa gilgitica*, *Carex oligocarya* sind ± an die montane *Picea schrenkiana*-Stufe (Gilgit, W Baltistan) gebunden; alp. sind *Colpodium baltistanicum*, *Calamagrostis stoliczkae*. *Carex borii* überschreitet die Hauptkette nach N (vgl. unter 2). Weitere Arten sind ± diffus um das Upper Indus Vy. gruppiert.

10. Inner-Himalayisch, *Kobresia nitens*-Typ - Eine große Artengruppe charakterisiert den inneren Himalaya und SW Karakorum bis zum Hunza-Durchbruch. Die Areale keilen nach E (wie unter 8.) entlang der Himalaya-Hauptkette (Chenab, Spiti, W Nepal) aus. *Carex plectobasis*, *C. pseudobicolor*, *Kobresia nitens*, *Festuca hartmannii*, *F. kashmiriana* erreichen ihre NW-Verbreitungsgrenze im Gilgit-Becken. Weiter westlich verbreitet (± einschließlich Nuristan, Chitral, W Pamir) sind *Allium consanguineum*, *Carex infuscata*, *Kobresia laxa*, *Alopecurus himalaicus*, *Aristida cyanantha*, *Agrostis vinealis*, *Bromus confinis*, *Pennisetum lanatum*, *Pennistum orientale*, *Phleum himalaicum*, *Piptatherum munroi*, *P. vicarium*, *Trisetum clarkei*, *Tulipa clusiana*. Einige Arten sind im himalayisch-zentralasiatischen Grenzgebiet nahezu linear verbreitet (Chitral-Gilgit-Dras-Spiti): *Allium fedtschenkoanum*, *Puccinellia minuta*, *Stipa pennata* subsp. *kirghisorum*, *St. turkestanica*.

11. Äußerer Himalaya, *Eremurus himalaicus*-Typ - Vorwiegend S-Himalayische Areale (Nuristan, Lower Chitral, Swat, Hazara, Kashmir, Himachal Pradesh) sind im Indus-Durchbruchstal bis Gilgit nur mit einzelnen Vorposten vertreten: *Eremurus himalaicus*, *Polygonatum geminiflorum*, *Carex cruenta*, *Carex setosa*, *Carex vulpinaris*, *Colpodium himalaicum*, *Neottia listeroides*.

12. Irano-Turanische Vorposten, *Carex decaulescens*-Typ - Nur in den äußersten W Karakorum (Yasin) greifen *Eremurus fuscus*, *Carex decaulescens*, *Festuca karatavica* über; einige Areale die weiter in das obere Indus-System ausgreifen (*Carex diluta*, *C. karoi*, *C. pamirensis*, *C. songarica*, *Deschampsia koelerioides*), vermitten zu 7.

8 Diskussion der Differenzierungsmuster - *Discussion of differentiation patterns*

8.1 Abiotische Faktoren - Abiotic factors

8.1.1 Aktuelles Klima - Actual climate

Aktuell-klimatische Faktoren scheinen ausweislich der untersuchten Monocotyledoneae einen wesentlichen Teil der horizontalen und vertikalen Areale zu determinieren. Mehrere Artenpaare zeigen eine ausgeprägte, in verschiedenen Verwandtschaftskreisen gleichlaufende vertikale oder peripher-zentrale Vikarianz. Da direkte klimatische Daten weitgehend fehlen, kommt der Flora und Vegetation eine wichtige Indikatorfunktion zu. Die Höhen- bzw. hygrische Zonierung zeigt einen charakteristischen absoluten Verlauf mit von SW nach NE stark ansteigender Tendenz (vgl. Arealkarten mit Höhendiagrammen im Anhang).

8.1.2 Klimageschichte und geographisch-geologische Faktoren - Climate history and geographical-geological factors

AGACHANJANC (1980) stellt die klimageschichtliche Grundlage der aktuellen Areale der zentralasiatischen Flora dar. HSÜ JEN (1982, 1984) untersucht die paläoökologischen Folgen der Auffaltung des Tibetanischen Plateaus.

BHATTACHARYYA (1989) präsentiert eine pollenanalytische Untersuchung der Sedimente des Tso Kar an der SE Grenze des Karakorum, rezent an der Grenze der Tibetanischen Florenregion gelegen. Paläoklimatische Untersuchungen aus dem Karakorum liegen abgesehen von DEEVEY (1937) offensichtlich nicht vor. Die geringe Verbreitung und das junge Alter von pollenführenden Ablagerungen (Moore, Seesedimente) im Karakorum hängt wahrscheinlich mit den insgesamt ariden Bedingungen und einer vollständigen eiszeitlichen Ausräumung entsprechender Sedimente zusammen. BHATTACHARYYA (1989) rekonstruiert für das frühe Holozän, ca. 30000 B.P., eine der heutigen Vegetation ähnliche alpine Steppe, die zwischen 21000-18000 B.P. und 18000-11800 B.P. von wärmeren Interstadialen (*Juniperus*, *Pinus*) unterbrochen wurde. DEVEEY (1937) fand keine interstadialen Warmzeiten, seine Altersbestimmungen sind allerdings unsicher. BEUG (1987) folgert aus der Untersuchung eines Pollenprofils aus NE Tibet, daß die Klimaverbesserung und der Rückzug der Gletscher am Ende des Würm-Glazials (9500 B.P.) bereits beendet war. Ältere Profile sind vom Tibetanischen Plateau allerdings anscheinend unbekannt. Ein Pollenprofil aus dem Wakhan (BORTENSCHLAGER & PATZELT 1978) umfaßt nur etwa 2000 Jahre mit Schwankungen, aber keiner anscheinend keiner grundsätzlichen Änderung des Klimas.

Eine Ableitung klimatischer Tendenzen aus der aktuellen Vegetation, wie sie MIEHE (1988) für die beobachtete Zerstörung von *Kobresia pygmaea*-Polstern an der Trockengrenze als Aridisierungstrend annimmt, ist zumindest nur von lokaler und zeitlich sehr begrenzter Aussagekraft (WEIERS 1993). Mehrere Indizien deuten auf eine Erwärmung und Nachlassen der Niederschlagsaktivität im SW Karakorum in den letzten 50 Jahren, unterbrochen allerdings von Jahren mit ungewöhnlich hohen Sommer-Niederschlägen (1986, 1992, 1993).

Die kleine Zahl und die verwandtschaftlichen Beziehungen der meist gering differenzierten Endemiten deuten auf ungünstige eiszeitliche Überlebensmöglichkeiten, eine prähistorisch wahrscheinlich nahezu vollständige Vergletscherung des Karakorum und stark schwankende, auch rezent ungünstige Lebensbedingungen. Die Endemiten konzentrieren sich im relativ isolierten Waldgrenzgebiet um den Indus-Durchbruch, der wahrscheinlich nicht vollständig vergletschert war und auch heute die günstigsten thermo-hygrischen Bedingungen bietet. Die Areale Tibetanischer Elemente könnten mit den Eisrandlagen des vermutlich geschlossenen pleistozänen Eisschildes über Tibets zusammenhängen, sind aber wahrscheinlich eher an die rezente Permafrostverbreitung gebunden.

© Biologiezentrum Linz/Austria; download unter www.biologiezentrum.at

Die Verbreitung endemischer Sippen mit einer auffälligen Konzentration um das Gilgit-Indus-Becken könnte ebenfalls mit der Glazialgeschichte zusammenhängen. Die hochalpine *Carex borii* besiedelt mit einem Verbreitungsschwerpunkt im SW Karakorum beide Seiten des Indus-Tales und ein charakteristisches Teilareal an der Grenze Zanskar / Himachal Pradesh. Das endemische Areal von *Carex oligocarya* ist wahrscheinlich als Relikt einer interstadial weiteren Verbreitung mesophiler Waldpflanzen zu deuten. *C. alaica* aus der *Picea schrenkiana*-Stufe des W Tian Shan, des Alai und der Kongur-Nordseite ist nächst verwandt, etwas entfernter *C. kashmirensis* der Himalaya-Südabdachung. *Allium gilgiticum* ist wahrscheinlich ein Relikt eines geschlossenen himalayischen Areals. Die Endemiten *Poa suruana* und *Poa gilgitica*, eng verwandt mit dem himalayischen *Poa falconeri*, sind gering differenzierte, nördlich der Hauptkette isolierte Segregate des Verwandtschaftskreises.

Zahlreiche zentralasiatische Sippen, die die Karakorum-Hauptkette nach S überschreiten und auch das Gebiet bis an den Rand des Himalaya besiedeln, deuten eine ältere geologische Geschichte, die wahrscheinlich mit der Plattentektonik zusammenhängt, an. Verbreitungsgrenzen zeigen häufig eine gewisse Übereinstimmung mit den tektonischen Großstrukturen (Suturen, Verwerfungen, Karte 2 - map 2). Die ± disjunkten Teilareale von *Allium oreoprasum*, *Stipa breviflora* und einigen weiteren Arten, könnten Reste einer kontinuierlichen Süd-Zentralasiatischen Verbreitung, vom Tarim-Becken entlang der Karakorum-Verwerfung (Karakoram Fault) zum Inneren Himalaya / S Tibet darstellen (Lößrelikte, "Tethys elements", vgl. HUANG RONGFU 1988). Die Häufung Himalayischer Elemente im SW Karakorum zeigt eine gute Übereinstimmung mit der Ausdehnung der Indischen Platte (Nanga-Parbat-Syntaxis); Häufungszentren endemischer Arten liegen hauptsächlich im Bereich der des Kohistan-Ladakh-Inselbogens zwischen der Indischen und Asiatischen Platte. Klimatische und stratigraphische Interferenzen lassen sich jedoch kaum von den vermuteten plattentektonischen Grundlagen trennen.

Über geochemische Präferenzen einzelner Arten liegen kaum Untersuchungen vor (vgl. 3.2). Areale alpiner Arten mit einer Konzentration im Zentral-Karakorum (*Carex borii*, *Carex nivalis*) deuten eventuell auf die Bevorzugung saurer Substrate (Granit), während z.B. *Carex pseudofoetida*, mit Verbreitungsschwerpunkt in den äußeren Ketten, wahrscheinlich (± kalkhaltige) Sedimente bevorzugt.

Die charakteristische Verbreitungslücke einiger im E Pamir und W Tibet verbreiteter Arten im Karakorum ("Karakorum Gap": *Blysmus rufus*, *Elymus thomsonii*, *Poa tibetica*, *Stipa mongholica*) läßt sich eventuell mit geomorphologisch-geologischen Faktoren erklären: Die Arten besiedeln hochgelegene, ± salzhaltige Sand- und Schotterstandorte, die in E Pamir und W Tibet weite Flächen der ehemaligen Plateaugletscher einnehmen. Im Karakorum fehlen diese Standorte aufgrund der hohen Reliefenergie weitgehend.

8.2 Anthropo-zoogene Faktoren, Pflanzenverbreitung, Bestäubungsbiologie - Anthropo-zoogenous factors, dispersal of plants, pollination biology

Anthropo-zoogene Faktoren scheinen zumindest für die aktuelle Arealgestalt der Monocotyledoneae des Karakorum eine untergeordnete Bedeutung zu besitzen. Einige mögliche Interferenzen:

Die zentrale und östliche Karakorum-Nordabdachung gehört zu den wenigen anthropogen noch nahezu unbeinflußten Gebieten der Erde. Die nördlich des K2 nächste Siedlung mit Ackerbau liegt auf der Kunlun-Nordabdachung (Kudi, 3000 m). Mazar (3800 m) im Yarkand Vy. ist eine Relaisstation an der durch das obere Yarkand-Tal verlaufenden Straße nach Tibet. Unterhalb Mazar ist die Straße verfallen, wird aber als Karawanenweg benutzt. Ackerbau wird in diesem Abschnitt des Yarkand-Tales nicht mehr betrieben (wenige aufgelassene Felder bei 3740 m), es finden sich aber noch zahlreiche (potentiell) anthropozoogen verbreitete Unkräuter (*Cirsium arvense*, *Chenopodium schraderianum*, *Eremopoa altaica*). Auch transhumante (Wander-) Weidewirtschaft endet am Kamm des Aghil Shan. Die letzte permanente menschliche Besiedlung gegen den Karakorum-Hauptkamm findet sich im Surukwat-Tal (3700 m Winter-, 4150 m Sommersiedlung einer einzigen Kirghisen-Familie) an der Nordseite des Aghil Shan. Entlang wichtiger Straßen (Khunjerab, Karakorum Highway; Xinjiang - Tibet Highway), Karawanen-, Handels- (Karakorum P.) und strategisch wichtiger Routen sowie der Zugangswege zu den prominentesten Gipfeln finden sich jedoch auch außerhalb des Siedlungsgebietes bereits deutliche Zeichen menschlichen Einflusses.

© Biologiezentrum Linz/Austria; download unter www.biologiezentrum.at

Am K2-Nord-Basecamp im Muztagh Vy. (Sughet Jangal), beispielsweise, fanden sich einige annuelle Arten, die wahrscheinlich mit Expeditionskamelen dort eingeschleppt wurden (*Bassia dasyphylla*, *Halogeton arachnoideus*, *Salsola* sp.). Obwohl zumeist ohne spezielle Verbreitungseinrichtungen, können eventuell auch Vorposten einiger Monocotyledoneae (*Carex cruenta*, *Danthonia cachemyriana*, *Eremopoa altaica*) weit außerhalb des Hauptverbreitungsgebiets und in relativ großer Meereshöhe als vorübergehende Verschleppung gedeutet werden.

Im gesamten S und W Karakorum besteht ein erheblicher und zunehmender Weidedruck, der sich floristisch offensichtlich in der häufigen Vorherrschaft dorniger Sippen (*Astragalus*, *Acantholimon*, *Echinops*, *Berberis*) oder solcher mit giftigen oder ungenießbaren Inhaltsstoffen (z.B. *Artemisia* spp.) gegenüber den meisten Grasartigen bemerkbar macht. Unter den Monocotyledoneae stellen z.B. *Stipa brandisii*, *St. splendens* und *Iris hookeriana* ausgesprochene Weideunkräuter dar.

Auch außerhalb des menschlichen Siedlungsgebietes existiert ein gewisser Weidedruck durch Wildtiere (Angaben nach GRZIMEK 1968-1972). Vorwiegend den Tibetanischen Grenzbereich (Changtang) charakterisieren Argali-Schaf - argali sheep (*Ovis ammon*), Blauschaf - blue sheep (*Pseudois nayaur*), Orongo - Tibetan antelope (*Pantholops hodgsoni*), Tibetgazelle - Tibetan gazelle (*Procapra picticaudata*), Wildyak - wild yak (*Bos mutus mutus*) und Kiang - Tibetan wild ass (*Equus hemionus kiang*), die teilweise noch in historischer Zeit in großen Herden vorkamen (DEASY 1901), heute aber bis auf Restbestände dezimiert sind (SCHALLER 1993). Die Bestände des Marco-Polo-Schafs (*Ovis ammon polii*) im Pamir sind ebenfalls stark rückläufig (NAUMANN 1978). *Pseudois nayaur* scheint nach eigenen Beobachtungen der einzige in der Karakorum-Nordabdachung verbreitete Großsäuger zu sein. Der sibirische Steinbock - ibex (*Capra ibex sibirica*) kommt auf der Südabdachung vor (HARTMANN 1966). Gleichfalls stark dezimiert dürften heute auch die Populationen der natürlichen Predatoren sein: Tibetanischer Braunbär - Tibetan brown bear (*Ursus arctos pruinosus*), im Himalaya: Isabell-Braunbär - Isabelline brown bear (*Ursus arctos isabellinus*), Tibetanischer Fuchs - Tibetan sand fox (*Vulpes ferrilatus*), Nordluchs - lynx (*Lynx lynx*) und Schneeleopard - snow leopard (*Uncia uncia*).

Schafe und Ziegen werden überall im menschlichen Siedlungsbereich gehalten. Von den Nutztieren hat der Hausyak - domestic yak (*Bos mutus grunniens*) im ariden Gebiet des CN Karakorum keine größere Bedeutung. Hier werden Baktrische Kamele als Transporttiere eingesetzt, von denen auch im Shimshal und Nubra des CS Karakorum kleinere Populationen gehalten werden.

Insbesondere die tibetanische Flora ist hochgradig beweidungsangepaßt. Unter den Monocotyledoneae bilden die harten Zwergpolster von *Kobresia pygmaea* eine Hauptfutterpflanze des Yak; der Kiang (*Equus hemionus kiang*) weist offensichtlich eine gewisse Bindung an seine Hauptfutterpflanze auf, *Carex moorcroftii* mit harten, stechenden Blättern (SCHALLER 1993).

Die Mehrzahl der wenigen endemischen Gattungen Tibets sind bemerkenswerterweise einjährige nitrophytische Lägerpflanzen: *Microgynoeceum tibeticum* (*Chenop.*, monotypisch), *Microula tibetica* (*Borag.*, ca. 10 weitere Arten), sowie die nicht im Karakorum nachgewiesenen: *Metaeritrichium microuloides* (*Borag.*, monotypisch), *Pomatosace filicula* (*Primul.*, monotypisch) und *Circaeaster agrestis* (*Ranunc./Circaeasteraceae*, monotypisch; primär eine Waldpflanze). Entsprechende Lebensformen finden sich unter den Monocotyledoneae nicht. *Lancea tibetica* (*Scroph.*, monotypisch), eine niedriger Rhizomgeophyt, und *Przewalskia tangutica* (*Solan.*, monotypisch) können ebenfalls zu den beweidungstoleranten Endemiten gerechnet werden. Dieses deutet eventuell auf eine lange Koevolution zumindest der Tibetanischen Flora mit Weidetieren.

Unter den Kleinsäugern charakterisieren Pfeifhasen - pikas (*Ochotona* spp.), z.B. *Ochotona roylei* (Tian Shan, Pamir, Himalaya, Tibet, 2500-6000 m) ebenfalls überwiegend den tibetanischen Bereich mit (hoch)alpinen Rasen. Verschiedene *Ochotona*-Arten kommen auch im Zentral-Karakorum vor. Durch ihre Grabetätigkeit, das Eintragen von Früchten und lokale Eutrophierung bei hohen Populationsdichten, scheinen sie eine gewisse Bedeutung für das Vegetationsgefüge von Rasengesellschaften, eutrophierten "Lägerfluren" und Deflationspflaster-Steppen zu besitzen. Seltener sind Tibetanischer Wollhase - Tibetan

© Biologiezentrum Linz/Austria; download unter www.biologiezentrum.at

wooly hare (*Lepus oiostolus*) und die an tiefgründigere Standorte angepaßten Murmeltiere - marmots (*Marmota caudata* mit westlicher, *Marmota himalayana* mit östlicher Verbreitung).

Als wichtige Vektoren für die Flora der im Zentral-Karakorum eng begrenzten Feuchtgebiete kommen Zugvögel aus Nord- und Zentralasien in Betracht. Zufallsbeobachtungen von Vogelarten im CN Karakorum im Herbst 1986 (DICKORÉ unpubl.) umfassen Krickente (*Anas crecca*), Sumpfhuhn (*Porzana* sp.), Temminckstrandläufer (*Calidris temminckii*), Stelzenläufer (*Himantopus himantopus*), Baumpieper (*Anthus* cf. *trivialis*), Schafstelze (*Motacilla flava*), Bachstelze (*Motacilla alba personata*) und Star (*Sturnus vulgaris*). Ein Teil dieser Arten versuchte zumindest, den Karakorum-Hauptkamm im Bereich des Muztagh P. und Sella-Sattel (6258 m) direkt westlich des K2-Gipfels zu überqueren.

Verbreitungsbiologisch sind in der Flora des Karakorum verschiedene Strategien vertreten, die Verbreitung durch den Wind erscheint am häufigsten. Auffällige Formen von Anemochorie kommen z.B. bei *Oxytropis ampullata* mit blasig aufgetriebenen Früchten und *Nepeta longibracteata* mit "wollknäulartigen" abbrechenden Fruchtständen vor. Für diese alpinen Arten beobachtete ich an Strahlungstagen eine effektive Hangaufwärtsverbreitung mit thermischen Luftströmungen. Die verbreitungsbiologischen Anpassungen der Monocotyledoneae sind grundsätzlich eingeschränkter. Die Anemochorie z.B. von *Stipa*, *Calamagrostis*, und selbst der alpinen *Carex nivalis*, mit großen flach-membranösen Schläuchen, dürfte ebenfalls mit der Notwendigkeit der Arterhaltung in hygrisch günstigen Höhenstufen zusammenhängen. Viele Pflanzen haben aber auch relativ große und schwere Diasporen ohne spezielle Verbreitungseinrichtung. Etwas rätselhaft erscheinen die auf Exozoochorie ausgelegten Klettfrüchte von *Eritrichium* in kaum zugänglichen Felsspalten und die Elaiosomen von *Viola* weit oberhalb des Vorkommens von Ameisen.

Die Invertebratenfauna der klimatisch extremen Karakorum-Nordabdachung ist arten- und meist auch individuenarm. In der alpinen Stufe sind nur Springschwänze und Spinnen an Biomasse und Artenzahl reicher. Trotzdem scheint an Insekten als Blütenbestäubern in der alpinen Stufe kein Mangel zu bestehen. Als wichtigste, in geringen Arten-, aber relativ hohen Individuenzahlen auftretende (potentielle) Blütenbestäuber konnten wir entlang des K2-N-Gletschers (z.B. an den gelben Köpfchen des verbreiteten *Tanacetum tibeticum*) verschiedene Dipterengruppen, solitäre Wespen (*Halictus* spp.) und zwei Großschmetterlinge (*Vanessa cardui*, *Macroglossum stellatarum*) feststellen. Die Schmetterlinge waren häufig bereits kurz nach Sonnenaufgang in schnellem Flug zu beobachten, auch über dem K2-North-Gl. in über 5000 m Meereshöhe.

Die aspektbildenden Pflanzenarten der subalpinen Trockenstufe des CN Karakorum (*Krascheninnikovia ceratoides*, *Ephedra intermedia*) und der collin-montanen Halbwüsten und Steppen des S Karakorum (*Stipagrostis plumosa, Haloxylon thomsonii, Artemisia fragrans*) sind anemophil, was mit den hier noch schlechteren Lebensmöglichkeiten für Insekten zusammenhängen könnte.

Phytophage Insekten (z.B. *Chrysomelidae*, *Curculionidae*) sind in der Karakorum-Nordabdachung schwach vertreten. Eine Ausnahme machen in Samen (z.B. von *Astragalus*, *Oxytropis*, *Corydalis*, *Ephedra*) parasitierenden Dipterenlarven. Die häufig beobachteten blasig aufgetriebenen Früchte von *Corydalis adiantifolia* "var. *heterocarpa* JAFRI" sind auf einen solchen Parasitenbefall zurückzuführen.

8.3 Interne Evolutionsfaktoren - Internal evolutionary factors

8.3.1 Lebensformen - Life forms

Die Lebensformen der Karakorum-Flora werden einzig von HARTMANN (1986, 1972) einer genaueren Betrachtung unterzogen. Da die Monocotyledoneae ein eingeschränktes Lebensform-Spektrum besitzen, sollen hier nur einige allgemeinere Aspekte zusammengefaßt werden. Hemikryptophyten und Chamaephyten dominieren in der Hochgebirgsflora des Karakorum.

Therophyten sind in der Tibetanischen Flora erstaunlich reichhaltig vertreten, insbesondere Arten der *Gentianaceae*, *Cruciferae* und anderer Dicotyledoneae (kaum Monocotyledoneae) finden auf dem

© Biologiezentrum Linz/Austria; download unter www.biologiezentrum.at

oberflächlich auftauendem Permafrost gute Lebensbedingungen. Arten wie *Gentianella pygmaea*, *G.* (*Comastoma*) *azurea* und *Koenigia islandica*, die auch im Karakorum vorkommen, dürften zu den am höchsten steigenden Einjährigen gehören. Frühjahrstherophyten, darunter auch einige *Gramineae* (*Phleum himalaicum*, *Eremopoa songorica*) sind weitgehend auf einen "Therophytengürtel", der in mittlerer Höhenstufe des S und W Karakorum bei relativer Wärme ausreichende Winterniederschläge erhält, beschränkt. Mehr oder weniger sukkulente Sommertherophyten (überwiegend *Chenopodiaceae*) kennzeichnen die collin - subalpinen Stufen der Zentralasiatischen Nord-Abdachung und die inneren Täler des S Karakorum.

Geophyten sind allgemein schwach repräsentiert, ein Schwerpunkt liegt ebenfalls im Grenzbereich zur Irano-Turanischen und Himalayischen Region im SW Karakorum (*Lilium polyphyllum*, *Tulipa clusiana*, *Gagea* spp., *Allium* spp., *Orchidaceae*). Die meisten *Allium*-Arten des Karakorum repräsentieren einen gewissen Übergang zur chamaephytischen Lebensform (Subgen. *Rhiziridium*: z.B. *A. przewalskianum*, *A. oreoprasum*), die sonst unter den Monocotyledoneae des Karakorum kaum vertreten ist.

Das Tibetanische Plateau im engeren Sinne, einschließlich Changtang und NE Karakorum charakterisieren die eigentümlichen Spaliersträucher *Hippophae tibetica*, *Myricaria prostata* und *Krascheninnikovia compacta* (N Tibet, Changtang), die jeweils altitudinale Vikarianten normal strauchförmiger Arten (*H. rhamnoides*, *M. bracteata*, *K. ceratoides*) darstellen. Vergleichbare Lebensformen und Differenzierungsmuster kommen bei den Monocotyledoneae nicht vor.

Unter den bei *Cyperaceae* und *Gramineae* weit dominierenden Hemikrytophyten ist zu beobachten, daß in den extremen Trockengebieten (CN Karakorum) außerhalb der Grundwasserbereiche streng horstförmiger Wuchs überwiegt (*Festuca olgae*, *Poa attenuata*, *Stipa subsessiliflora*). Arten mit Stolonen oder kriechenden Rhizomen sind an relativ feuchtere und lockerere Böden gebunden, so z.B. *Poa pratensis* s.l. im SW Karakorum. *Carex atrofusca* und *Poa calliopsis* sind Beispiele rhizomatöser Arten in feuchten alpinen Rasen und Quellsümpfen. Neben Sandern und Flußterrassen mit ausgesprochenen Psammophyten wie *Leymus secalinus* und *Orinus thoroldii,* haben auch die hochalpinen Frostschutt-Flächen des Tibetanischen Plateaus einen höheren Anteil von Rhizom-Hemikrytophyten (*Carex moorcroftii*, *Poa tibetica*).

8.3.2 Populationsdynamik und taxonomische Differenzierungsmuster - Population dynamics and taxonomic differentiation patterns

Taxonomisch repräsentiert die Flora des Karakorum ein artenarmes, aber hochgradig vernetztes System aus einander häufig sehr nahestehenden Sippen. Die Gesamtpopulationen (Areale) einzelner Sippen sind meist sehr groß (zentralasiatisch, eurasiatisch, holarktisch), bestehen aber häufig aus relativ kleinen, untereinander isolierten Subpopulationen. Viele Arten zeigen in Abhängigkeit von den ökologischen Bedingungen eine außerordentliche phänotypische Plastizität, die anscheinend häufig auch mit einer klinalen oder diskontinuierlichen lokalen Variabilität gekoppelt ist (z.B. *Kobresia royleana* und *K. schoenoides*). *K. royleana* ist wie viele andere Sippen des Karakorum von Nachbararten (*K. humilis*, *K. karakorumensis*) zwar anscheinend spezifisch getrennt, aber im Kontaktbereich durch (hybridogene ?) Zwischenformen verbunden. Ähnliches gilt wahrscheinlich für die tibetanischen Verwandten von *K. schoenoides*, die auch ein gutes Beispiel für einen charakteristischen Biotopwechsel ("relative Standortskonstanz") bildet: während *K. schoenoides* im relativ humiden SW Karakorum alpine Weiderasen ohne ausgesprochenen Wasserzuschuß besiedelt, ist sie auf der trockenen Nordseite streng an Quell- und Grundwasserstandorte gebunden. *Thylacospermum caespitosum* (Caryoph.), auf dem Tibetanischen Plateau eine charakteristische Polsterpflanze auf Blockschuttstandorten, ist im ariden K2-North ein reiner Chasmophyt.

Viele alpine und subnivale Sippen bilden aufgrund wechselnder und langjährig ungünstiger Keimungsbedingungen anscheinend sehr langlebige und langsamwüchsige Populationen, die sich vorwiegend vegetativ vermehren. Auf der anderen Seite erforden physikalisch instabile Bedingungen (z.B.

© Biologiezentrum Linz/Austria; download unter www.biologiezentrum.at

Gletscher-Vorfelder) aber auch eine hohe Innovationsfähigkeit und Kolonisationsfähigkeit (vgl. DICKORÉ 1991).

Die untereinander eng verwandeten Taxa einiger Gruppen (z.B. *Carex stenophylla*, *C. pseudofoetida*, *C. sagaensis*; *Carex alexeenkoana*, *C. plectobasis*, *C. haematostoma*; *Elymus* spp.; *Poa nemoralis* agg.; *Poa pratensis* agg.) bilden scheinbar kontinuierliche Komplexe mit an altitudinalen, peripher-zentralen oder ökologischen Grenzlinien scheinbar ineinander "umschlagenden" Sippen. Die Artabgrenzung ist innerhalb dieser Komplexe häufig extrem schwierig. Über die Evolutionsmechanismen ist nichts bekannt, die Deutung von Zwischenformen als Bastarde (z.B. *Elymus*) rein morphologisch begründet. Allopatrische Speziation scheint eine wichtige Rolle zu spielen, ebenso aber auch sympatrische (allopolyploide ?) Artbildung und ökologische Konservierung entlang klimatischer Grenzlinien.

Konvergenzen sind oft sehr weitreichend, z.B. kann der Habitus von (Kümmerformen von) *Blysmus compressus*, *B. rufus*, *Kobresia pygmaea*, *Carex microglochin*, *C. parva*, *C. stenophylla*, *C. pseudofoetida* und *C. sagaensis* praktisch identisch sein. Zu einem gewissen Maß ist diese „Konvergenz" jedoch auch ein Ausdruck näherer Verwandschaft. Die nah verwandten, aber üblicherweise distinkten Arten von *Kobresia* § *Elyna* (*K. capillifolia*, *K. schoenoides*, *K. nitens*, *K. robusta*) bilden im Extremfall ebenfalls nahezu identische Wuchsformen.

8.3.3 Genetik und Cytologie - Genetics and cytology

Die genetische und cytologische Differenzierung der Flora des Karakorum kann als weitgehend unbekannt gelten. Cytologische Daten aus angrenzenden Gebieten geben für die Flora des W Himalaya z.B. MERAH & REMANANDAN (1973), MERAH & SHARMA (1975, 1977), VASUDEVAN (1975, 1976), FARUQI & al. (1979), SHARMA (1985), NADEEM AHSAN & al. (1994), MOINUDDIN & al. (1994); HUSS (1980) für einige Arten aus dem Wakhan. Eine bessere Kenntnis der genetischen Differenzierung der Karakorum-Flora könnte, auf der Grundlage tragfähiger morphologischer Konzepte, zu einem besseren Verständnis der oben diskutierten Probleme führen. Viele der morphologisch schwierigen Formenkreise der Flora des Karakorum, mit vikariierenden oder anscheinend hybridogenen oder introgressiven Sippen, bedürfen einer weiteren Aufklärung jenseits der Grenzen (makro-)morphologischer Methoden. Eigene Untersuchungen wurden nicht durchgeführt.

Einige wirtschaftlich wichtige Sippen, wie *Poa pratensis* s.l., aber auch sekundäre Genpools von Nahrungspflanzen (*Allium*, *Hordeum*) sind in der Flora des Karakorum mit geographisch zentralen und hochadaptierten Vertretern enthalten. Auch die Aufklärung der Klimageschichte und der Wanderungswege einzelner Sippen hängt wesentlich von einer besseren Kenntnis der genetischen Grundlagen der floristischen Differenzierung ab.

Die meist junge (? interglaziale) Speziation der Endemiten des Karakorum dürfte in vielen Fällen auf Isolation und Segregation (vorwiegend) himalayischer Elemente nördlich der Himalaya-Hauptkette und zentralasiatischer Verwandschaftskreise im Gilgit-Indus-Becken beruhen. Die periglaziale Invasion in Gletscherrückzugsgebiete begünstigte anscheinend auch die Durchsetzung und Stabilisation von hybridogenen oder introgressiven Sippen (vermutet z.B. *Calamagrostis stoliczkae*, *Colpodium baltistanicum*, *Elymus stewartii*). In welchem Maße (Allo-) Polyploidie und Apomixis eine Rolle spielen, bedarf entsprechender Untersuchungen.

Zusammenfassung

Im Rahmen einer kritischen Revision der Monocotyledoneae werden 282 Arten aus 17 Familien für den Karakorum sicher belegt bzw. als wahrscheinlich vorkommend angegeben. Vier neue Arten werden beschrieben und sieben neue Kombinationen werden angeführt. Chorologische und ökologische Daten werden für die im Karakorum vorkommenden Taxa zusammengestellt. Soweit derzeit möglich, wurden neue oder revidierte Bestimmungsschlüssel für einige Gattungen erstellt. Die Flora des Karakorum ist artenarm, aber von ausgesprochenem Übergangscharakter und durch taxonomisch komplexe und weit verbreitete Gruppen geprägt. Nah verwandte oder vikariierende Arten angrenzender Gebirgssysteme erfahren daher in der vorliegenden Arbeit eine orientierende Berücksichtigung.

Das Karakorum-System verbindet die Hochgebirgsplateaus von Ost-Pamir und West-Tibet und wird im Norden durch die Hochgebirgskette des Kunlun Shan, im Süden durch die Ketten des Himalaya und Hindukush begrenzt. Das gewaltige Gebirgsmassiv des Karakorum, gipfelnd im K2 (8611 m), dem zweithöchsten Berg der Erde, bildet einen zentralkontinentalen Schnittpunkt der Eurasiatischen Flora. Der Karakorum bildet eine außerordentlich scharfe Grenze zwischen der Holarktis und subtropischen Regionen sowie Barrieren zwischen den Zentralasiatischen, Irano-Turanischen und Sino-Himalayischen Florenregionen mit grundlegend unterschiedlichen klimatischen Bedingungen. Andererseits stellen die Ränder der großflächig vergletscherten Gebirgsketten des Karakorum einen bedeutenden Wanderweg und Filter dar, der die Südost-Tibetanischen Diversitätszentren zahlreicher „arktisch-alpiner" Florenelemente mit Hochgebirgen und hohen Breitengraden der Holarktis verbindet.

Generell dominieren im kalt-ariden Karakorum Zentralasiatische Elemente. Flora und Vegetation sind jedoch altitudinal und peripher-zentral stark gegliedert. Auffallend ist eine extreme Verarmung des Floreninventars von Südwesten nach Nordosten, bei einem starken Anstieg des altitudinalen Vorkommensbereiches einzelner Sippen und Vegetationsformationen. Die artenreiche Sino-Himalayische Flora fehlt nördlich der Himalaya-Hauptkette weitgehend, eine relativ reiche (Inner-) Westhimalayische Flora ist jedoch durch die Indus-Schlucht bis in den Südwest-Karakorum (Gilgit) verbreitet. Um das Gilgit-Becken sind auch die insgesamt relativ wenigen endemischen Arten des Karakorum zentriert. Das obere Chitral, ein größerer Teil des Süd-Karakorum (Yasin, Hunza, Baltistan) und ein schmaler Keil entlang der Himalaya-Hauptkette bis Südost-Zanskar sind ebenfalls relativ reich an Himalayischen Elementen, die nördlich der Karakorum-Hauptkette praktisch völlig ausfallen. Irano-Turanische Elemente werden hauptsächlich durch die Ketten an den Grenzen von Afghanistan und Chitral ausgeschlossen, ein reduzierter Artensatz ist jedoch in den inneren Tälern des Süd-Karakorum weit verbreitet. Zentralasiatische und Ost-Pamirische Elemente charakterisieren den Norden und Nordwesten des Karakorum. Einige Areale erstrecken sich, mehr oder weniger disjunkt, auf die Südabdachung bis Ladakh und Süd-Tibet. Die Verbreitungsgebiete einiger der im Nordosten dominierenden Tibetanischen (Hochasiatischen) Elemente zeigen eine charakteristische Disjunktion („Karakorum gap") zwischen Ost-Pamir und West-Tibet.

Der in verschiedenen Verwandtschaftskreisen gleichlaufende altitudinale und regionale Florenwechsel (vikariierende Arten) wird offenbar in erster Linie durch die außerordentlich steilen klimatischen Gradienten im Karakorum determiniert. Geologische, ökologische und entwicklungsgeschichtlich-systematische Aspekte der Flora des Karakorum werden diskutiert. Einige charakteristische Verbreitungsbilder deuten auf Zusammenhänge mit paläoökologische Bedingungen und Ereignissen und können eventuell als Indikatoren für die Geschichte der pleistozänen Eiszeiten oder sogar der tertiären Plattentektonik dienen.

Verzeichnis der Verbreitungskarten / Konsolidierter Index der Flora des Karakorum I. Monocotyledoneae - Index to distribution maps / Consolidated index to the Flora of the Karakorum I. Monocotyledoneae

In der folgenden konsolidierten Liste der Monocotyledoneae sind Verbreitungskarten mit Diagramm der Höhenverbreitung im Karakorum mit „ * " gekennzeichnet, zusätzlich dargestellte Arten mit „ + " und Hinweis auf die Artnummer der jeweiligen Verbreitungskarte.

Distribution maps with diagram of altitudinal distribution in the Karakorum are marked " * ".
Additional distribution maps are marked " + " , with reference to species number of map concerned.

Alismataceae

1. **Alisma plantago-aquatica** L.

Alliaceae

2. **Allium caesioides** WENDELBO
3. * **Allium carolinianum** DC. in REDOUTÉ
4. * **Allium consanguineum** KUNTH
5. * **Allium fedtschenkoanum** REGEL
6. * **Allium filifolium** REGEL
7. * **Allium gilgiticum** WANG & TANG
8. **Allium glomeratum** PROKHANOV
9. + **Allium hymenorrhizum** LEDEB. (→7)
10. **Allium jacquemontii** KUNTH
11. * **Allium oreoprasum** SCHRENK
12. + **Allium platyspathum** SCHRENK (→7)
13. * **Allium przewalskianum** REGEL
14. **Allium tuberosum** ROTTLER ex SPRENGEL

Asparagaceae

15. **Asparagus neglectus** KAR. & KIR.

Asphodelaceae

16. * **Eremurus fuscus** (O. FEDTSCH.) VVED. ex NIKITIN
17. + **Eremurus himalaicus** BAKER (→16)
18. + **Eremurus korshinskii** O. FEDTSCH. (→16)

Colchicaceae

19. **Colchicum luteum** BAKER

Convallariaceae

20. **Polygonatum geminiflorum** DECNE. in JACQUEM.
21. **Polygonatum leptophyllum** (D. DON) ROYLE

Cyperaceae

22. * **Blysmus compressus** (L.) PANZER ex LINK
23. * **Blysmus rufus** (HUDSON) LINK
24. **Bolboschoenus maritimus** (L.) PALLA in W. D. J. KOCH
25. * **Carex alexeenkoana** LITV.
26. * **Carex atrofusca** SCHKUHR
27. * **Carex borii** NELMES
28. * **Carex cruenta** NEES in WIGHT
29. * **Carex curaica** KUNTH
30. * **Carex decaulescens** V. KRECZ. subsp. **alsia** (RAYMOND) KUKKONEN
31. * **Carex diluta** M. BIEB.
32. * **Carex infuscata** NEES in WIGHT
33. * **Carex karoi** (FREYN) FREYN
34. * **Carex melanantha** C. A. MEYER in LEDEB.
35. * **Carex microglochin** WAHLENB.
36. * **Carex moorcroftii** FALC. ex BOOTT
37. * **Carex nivalis** BOOTT
38. * **Carex oligocarya** C. B. CLARKE in HOOKER f.
39. * **Carex orbicularis** BOOTT
40. * **Carex pamirensis** C. B. CLARKE
41. + **Carex parva** NEES in WIGHT (→35)
42. * **Carex plectobasis** V. KRECZ.
43. * **Carex pseudobicolor** BOECK.
44. * **Carex pseudofoetida** KÜKENTHAL
45. * **Carex sagaensis** Y. C. YANG
46. * **Carex setosa** BOOTT
47. + **Carex songorica** KAR. & KIR. (→40)
48. * **Carex stenocarpa** TURCZ. ex V. KRECZ. in KOMAROV
49. * **Carex stenophylla** WAHLENB.
50. + **Carex viridula** MICHX. (→31)
51. + **Carex vulpinaris** NEES in WIGHT (→29)
52. **Cladium mariscus** (L.) POHL
53. **Cyperus cuspidatus** KUNTH
54. **Cyperus haspan** L.
55. **Cyperus rotundus** L.
56. **Cyperus squarrosus** L.

57. + **Eleocharis palustris** (L.) ROEMER & SCHULTES (→59)
58. * **Eleocharis quinqueflora** (F. X. HARTMANN) O. SCHWARZ
59. * **Eleocharis uniglumis** (LINK) SCHULTES in SCHULTES & SCHULTES f.
60. **Fimbristylis bisumbellata** (FORSKAL) BUBANI
61. **Fimbristylis sieberiana** KUNTH
62. **Isolepis setacea** (L.) R. BR.
63. * **Kobresia capillifolia** (DECNE.) C. B. CLARKE
64. * **Kobresia karakorumensis** DICKORÉ
65. * **Kobresia laxa** NEES in WIGHT
66. + **Kobresia macrantha** BOECK. (→68)
67. * **Kobresia nitens** C. B. CLARKE
68. * **Kobresia pygmaea** (C. B. CLARKE) C. B. CLARKE in HOOKER f.
69. + **Kobresia robusta** MAXIM. (→68)
70. * **Kobresia royleana** (NEES) BOECK.
71. * **Kobresia schoenoides** (C. A. MEYER) STEUDEL
72. **Pycreus flavescens** (L.) REICHENB. in MÖSSLER
73. **Pycreus flavidus** (RETZ.) KOYAMA
74. **Pycreus sanguinolentus** (VAHL) NEES
75. **Schoenoplectus lacustris** (L.) PALLA
76. ***Schoenoplectus tabernaemontani*** (C. C. GMELIN) PALLA
77. **Schoenoplectus triqueter** (L.) PALLA
78. * **Trichophorum pumilum** (VAHL) SCHINZ & THELL.

Gramineae (Poaceae)

79. * **Agrostis gigantea** ROTH
80. **Agrostis munroana** AITCH. & HEMSLEY
81. **Agrostis pilosula** TRIN.
82. **Agrostis stolonifera** L.
83. * **Agrostis vinealis** SCHREBER
84. **Agrostis viridis** GOUAN
85. * **Alopecurus arundinaceus** POIRET in LAM.
86. * **Alopecurus himalaicus** HOOKER f.
87. **Aristida adscensionis** L.
88. * **Aristida cyanantha** (NEES) STEUDEL
89. **Arthraxon lancifolius** (TRIN.) HOCHST.
90. **Avena fatua** L.
91. **Avena sterilis** L.
    subsp. **ludoviciana** (DUR.) GILLET & MAGNE
92. **Bothriochloa bladhii** (RETZ.) S. T. BLAKE
93. * **Bothriochloa ischaemum** (L.) KENG
94. **Brachypodium sylvaticum** (HUDSON) P. BEAUV.
95. * **Bromus confinis** NEES ex STEUDEL
96. * **Bromus gracillimus** BUNGE
97. + **Bromus japonicus** THUNB. ex MURRAY (→98)
98. * **Bromus pectinatus** THUNB.
99. + **Bromus stenostachyus** BOISS. (→95)
100. * **Bromus tectorum** L.
101. **Calamagrostis alaica** LITV.
102. * **Calamagrostis anthoxanthoides** (MUNRO) REGEL
103. **Calamagrostis decora** HOOKER f.
104. * **Calamagrostis epigejos** (L.) ROTH
105. * **Calamagrostis holciformis** JAUB. & SPACH
106. * **Calamagrostis pseudophragmites** (HALLER f.) KOELER
107. * **Calamagrostis stoliczkae** HOOKER f.
108. * **Calamagrostis tianschanica** RUPR. in OSTEN-SACKEN & RUPR.
109. * **Catabrosa aquatica** (L.) P. BEAUV.
110. **Chrysopogon gryllus** (L.) TRIN.

Ausgewählte Verbreitungskarten
- Selected distribution maps

Ausgewählt wurden die im Karakorum häufigsten Sippen und besonders charakteristische Verbreitungsbilder möglichst gleichmäßig erfaßter Taxa. Unterrepräsentiert sind vor allem himalayische und subtropische Areale, die den Karakorum meist nur im äußersten SW erreichen und deren Verbreitung in den Randgebieten häufig nur unzureichend untersucht werden konnte.

Nachweise aus der Literatur sind Fl.Tadzh., Pl.As.Centr., Fl.Iran. und Fl.Pak., sowie den weiteren zitierten Quellen entnommen. Literaturangaben für Randgebiete (außerhalb des Karakorum wie definiert) sind nur teilweise im Text angegeben. Gesehene Belege aus Randgebieten sind überwiegend, aber nicht grundsätzlich im Text zitiert.

Die Erfassung von Fundpunkten aus Randgebieten ist bei einzelnen Sippen aufgrund ungleichmäßiger Durchforschung, unterschiedlicher Sippenauffassungen und Schwierigkeiten bei der Lokalisierung sehr heterogen. Abgesehen von den Tiefländern sind insbesondere Belege und Literaturangaben aus Afghanistan und Tadzhikistan (außer Pamir) sowie dem zentralen Himalaya (Himachal Pradesh ostwärts) unterrepräsentiert. Die armen Floren W Tibets und des Kunlun Shan sind vergleichsweise gut belegt. Die Auswahl der in Verbreitungskarten dargestellten Sippen kompensiert die bei der Interpretation von Verbreitungsbildern zu berücksichtigen Ungleichmäßigkeiten nur teilweise.

Aussagekräftig sind vor allem die Verbreitungskarten vieler relativ weit verbreiteter *Cyperaceae* und *Gramineae*. Auf die Darstellung sehr unvollständig erfaßter Areale, z.B. Arten der *Juncaceae* und *Orchidaceae*, wurde verzichtet.

Symbole in den Verbreitungskarten - symbols used on distribution maps:

- ● Gesehener Beleg - Specimen seen
- ○ Literaturangabe - Literature record
- ⊙ Geographische Unschärfe - Geographical uncertainty
- ⊕ Fraglicher Nachweis - Doubtful record

Höhenschichten - Altitudinal intervals:

- < 1000 m
- 1000-2000 m
- 2000-4000 m
- 4000-5000 m
- > 5000 m.

Gebirgskämme > 5000-6000 m hervorgehoben - Crests above of > 5000-6000 m marked.

Tafel 1 - Pl. 1: **Landschaften der Karakorum-Nordabdachung** - Landscapes of the Karakorum N declivity.
1. K2-Nordseite, Gipfel (8611 m) 15 km entfernt, Ansicht von 4580 m über den K2-N Gl. Obergrenze alpin-subnivaler Vegetationsflecken (*Carex borii*, *Thylacospermum caespitosum*, *Sibbaldia tetrandra*) im Mittelgrund unterhalb der aktuellen Schneegrenze bei 5000-5200 m (Foto: 1986-09-08, *B.Dickoré*). 2. K2, Ansicht vom unteren K2-N Vy. (4000 m). Subalpine Wüste (*Krascheninnikovia ceratoides*, *Stipa caucasica* subsp. *glareosa*) im Vordergrund (Foto: 1986-09-02, *B.Dickoré*). 3. Lower Surukwat Vy. (Yarkand, 3550 m). Montan-subalpine Wüste (*Krascheninnikovia ceratoides*, *Ephedra intermedia*) auf glaziofluvialen Schotterterrassen, Talboden nahezu vegetationslos (Foto: 1986-10-23, *B.Dickoré*).

Tafel 3 - Pl. 3: **Gramineae.**
1. **Elymus nutans**, N Mazar 4000 m (Yarkand). Häufige Art auf Flußschotter (*Myricaria bracteata*) der subalpinen Stufe (Foto: 1986-08-20, *B.Dickoré*). 2. **Stipa orientalis**, Aghil Gorge 3920 m (Yarkand). Subalpine Art, häufig im W und S Karakorum, selten im NE (Foto: 1986-08-29, *B.Dickoré*). 3. **Stipa caucasica** subsp. **glareosa**, K2-N Vy. 4100 m (K2-North). Häufige und charakteristische Art subalpiner (Halb-) Wüsten im NE Karakorum und Ladakh (Foto: 1986-09-04, *B.Dickoré*).
